Central Problems of Solar Flare Physics

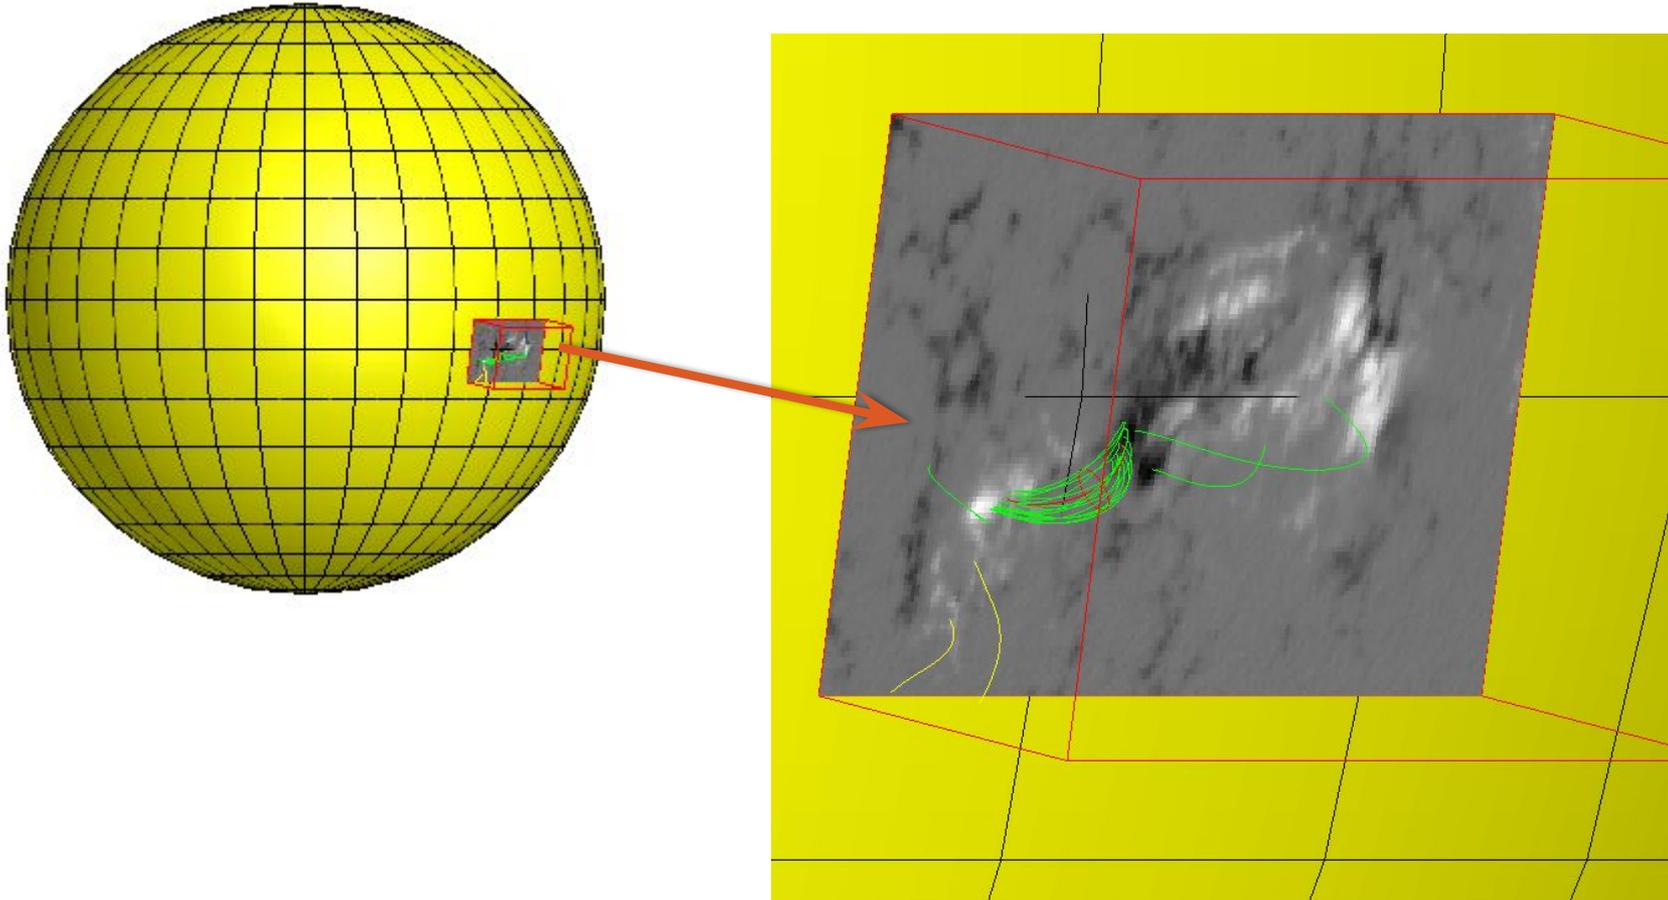

1. The problem of flare energy storage
2. The problem of particle acceleration, transport and radiation in plasma magnetic loops

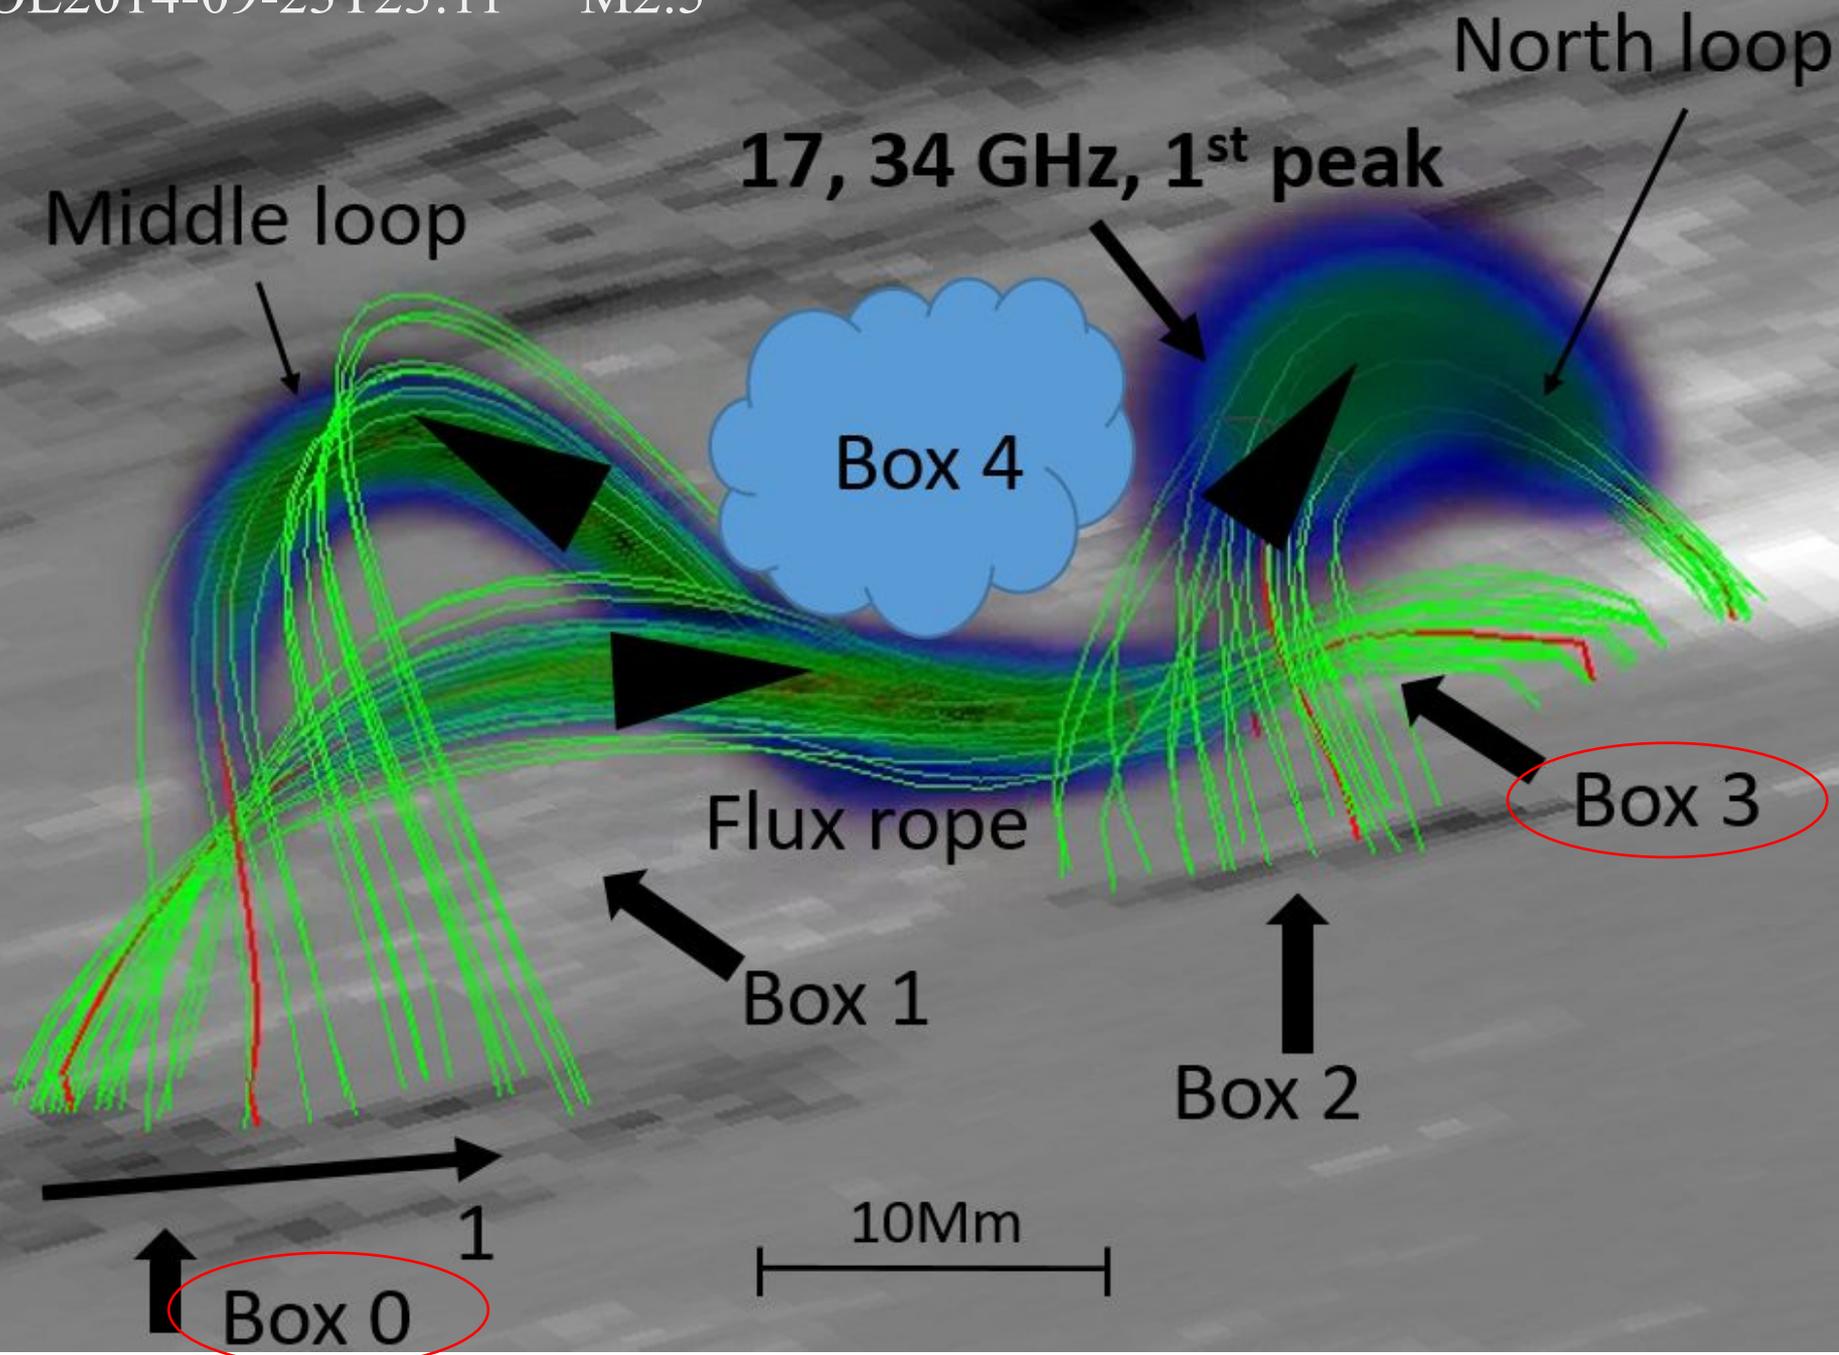

sketch from Kontar et al., 2017

GX Simulator **SOL2002:11:10 T 03:11,**
M2.6

Nita et al, 2014

There are basically two faces of a solar flare — one concerns energetic particles and their transport and radiation effects, and the other concerns the hydrodynamic evolution of the plasma in the flare loop. These two aspects are actually coupled together in a circular chain. Particles, on the one hand, lose their energy via Coulomb collisions and heat the background plasma, which causes chromospheric evaporation that changes the density and temperature distribution in the loop. In turn, such changes affect the particle acceleration and transport processes and influence the spectrum of the accelerated particles. The energy deposition rate (by particles) will also be altered and fed back to the hydrodynamics of the background plasma.

Due to the complexity of the subject, however, people tend to decouple these processes and study one at a time while assuming some simple forms for the others. For particle acceleration and transport, as mentioned earlier, one of the main streams of studies solves the Fokker-Planck equation and keeps track of the particle distribution function (e.g., Leach 1984; McTiernan 1989), assuming a static background atmosphere.

Problem of Electron Transport

1. Restore the distribution function of accelerated electrons at the time of injection into the plasma of the magnetic loop.
2. Plasma and magnetic field diagnostics

To develop a method for determining the characteristics of background plasma (plasma density, temperature) and accelerated electrons (spectrum, localization, pitch-angular distribution) in flares based on observations of X-ray and microwave radiation. In general, the kinetic equation with different initial electron distributions and plasma parameters is solved numerically and the influence of different processes on the beam and radiation dynamics is revealed.

Space and ground-based observations:

- Soft X-rays: **GOES** (1-8Å (1.5-12 keV), 0.5-4Å (3.1 – 24.8 keV)), **RHESSI** (3keV-20MeV)
- **HXR**: **RHESSI**, **Konus-Wind** (~20keV-20MeV), **BATSE** (20keV-1.9MeV), (**Fermi**)
- **GS radiation**: **NORH** (17, 34 GHz), **NORP** (1, 2, 3.75, 9, 17, 35, 80 GHz), (**EOVSA**, **CCPT**)
- **UV image**: **AIA/SDO** (9 lines 1700-94Å / 5000K-20MK), (**EIT/SOHO**)
- **Magnetic field structure**: **HMI/SDO**, **MDI/SOHO**

Software:

- Fokker-Planck kinetic code
- e-i, e-e bremsstrahlung of relativistic electrons: energy spectra, polarization degree, directivity
- Albedo calculation code
- SOLAR SOFT: GX Simulator (NLFFF/LFFF), HESSI, OSPEX, AIA, etc

Parameters affect the solar flare HXR and GS radiation

	Parameter	HXR >25 keV	GS (3-35GHz)
SDO/HMI SOHO/MDI	Angle of view, θ	+	+
	Magnetic field, $B(s,t)$	+ (due to the electron distribution function)	+
Set by indirect estimates or calculated self-consistently	Plasma density distribution along the magnetic loop, n_e	+	+
	Ionization degree of chromosphere plasma in the loop, x	+ (due to the electron distribution function)	-
Fokker – Planck equation	Injection function: $S(E, \mu, s, t)$ $\delta, E_{start}, E_{end}, E_{break}, S_1(s), S_2(\alpha), S_4(t)$ Albedo	+	+

FOKKER – PLANCK EQUATION

 \end{aligned}$$

$$C_1 = x + \frac{1-x}{2} \frac{\ln \beta^2 g^2 E / \alpha_F^4}{\ln \Lambda}, \quad C_2 = \frac{1}{2} + \frac{1+g}{4} C_1, \quad W(k_{\parallel}) = \frac{(\delta B)^2}{\pi} \frac{(1/\lambda_B)}{(1/\lambda_B)^2 + k_{\parallel}^2} \quad (\text{Kontar et al., 2013})$$

$$\lambda_0(s) = \frac{10^{24}}{n(s) \ln \Lambda}, \quad \beta = \frac{v}{c}, \quad \mu = \cos \alpha, \quad \gamma = E + 1, \quad E = \frac{E_e}{m_e c^2}$$

$$k_{\parallel} = \Omega_{ce} / v |\mu|$$

$$\Omega_{ce} = eB / m_e \gamma c$$

$$C(z) \propto \exp(-z/\lambda_B)$$

$$z(t) = \mu v t$$

$$\frac{1}{\sigma} = \frac{7.26 \cdot 10^{-9}}{x \cdot T_e^{1.5}} \ln \Lambda + \frac{7.6 \cdot 10^{-18} (1-x) T_e^{0.5}}{x}$$

Parameters obtained from observations and used in modeling

RHESSI

- X-ray flux
- Energy X-ray spectra $<130\text{keV}$
- Space locations of the X-rays of 28-58, 70-130 keV
- Estimated volume of the HXR sources
- Estimated plasma density - SXR

Nobeyama Radioheliograph

- Relative source location 17 , 34 GHz
- 17/34 GHz source brightness ratio

MDI +GS simulator

- Magnetic field structure - LFFF

The DATA analyses:

HXR observations:

- Analysis of time dynamics of HXR sources.
- Association with specific magnetic field structures
- Obtaining restrictions on the HXR spectrum in the range up to ~ 130 keV taking into account the spread of values at a previously unknown albedo effect (OSPEX), plasma density distribution and degree of ionization in the chromosphere.

UV - radiation:

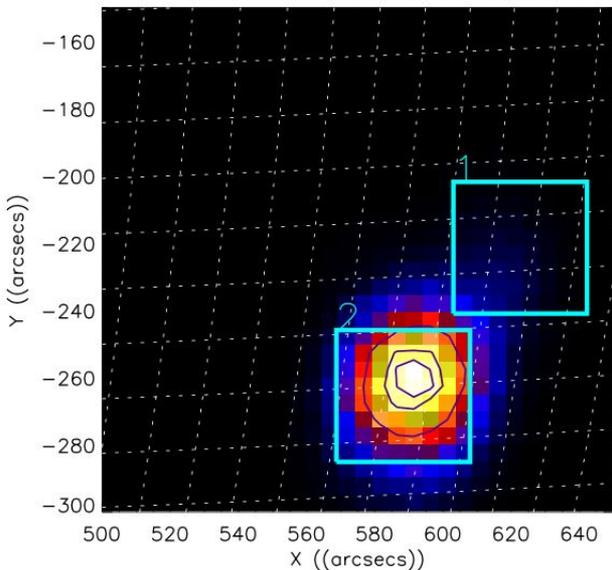

- Analysis of the loop structures

GS 17, 34 GGH:

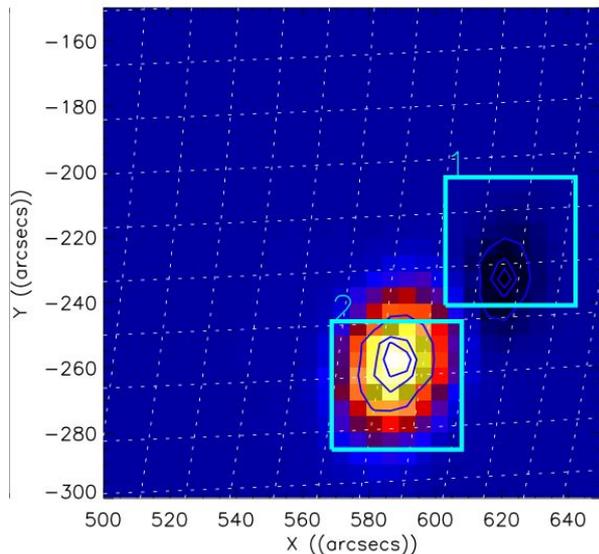

- Estimation of the electron spectrum >200 keV in GX
- Analysis of time dynamics of GS sources
- Association with specific field structures
- Estimates of n_b , E_b , n_e (Razin effect) and self-absorption are carried out after the first kinetic test models

CONSIDERED TYPES OF MODELS IN THE SOURCE

SOURCE FUNCTION $S(E, \mu, s, t)$ varied

($\mu = \cos(\alpha)$):

By angular distribution:

- Isotropic source
- Symmetric and asymmetric with varying degrees of anisotropy

By source localization: at the top, between the base and the top, and others.

By type of spectrum:

- 1 power law, broken power law
- consisting of two populations of electrons

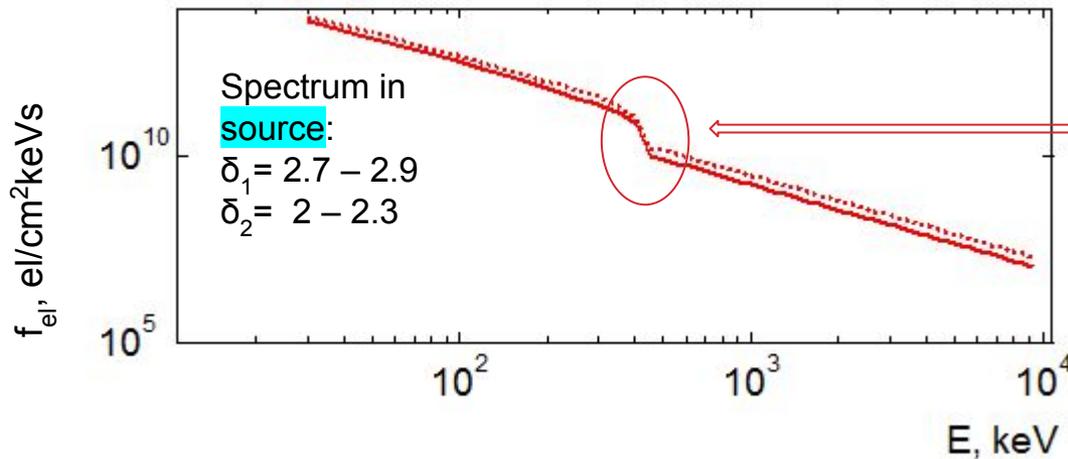

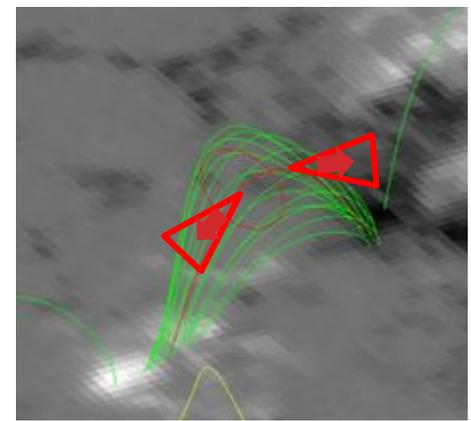

By the presence of additional scattering mechanisms: magnetic fluctuations, ion-sound turbulence

The time profile for the source is taken from the 80-130 keV RHESSI data range

$S_2(\alpha) =$	1	isotropic
	$\cos^{2n}(\alpha)$	longitudinal
	$\sin^{2n}(\alpha)$	transverse
	$\exp\{-(\alpha - \alpha_1)^2 / \alpha_0^2\}$	asymmetric

Finally, a model with parameters in a narrow range satisfied all observational criteria:

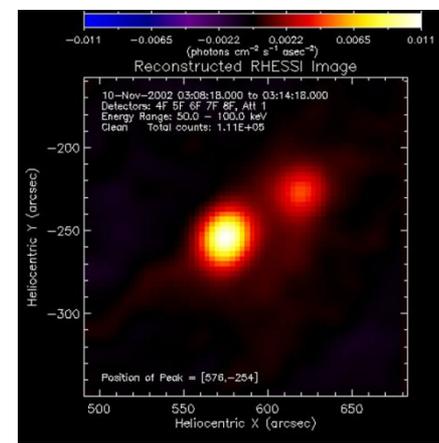

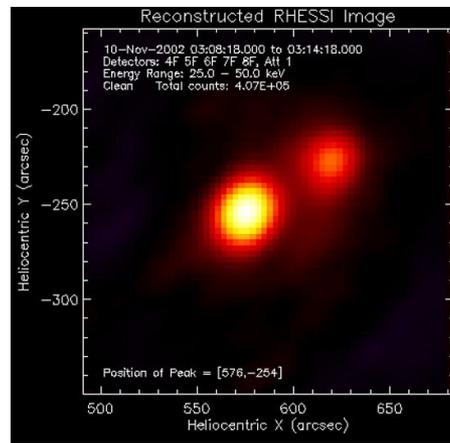

- Anisotropic source at the looptop $S(\alpha) = A(t)\exp\{-(\alpha - \alpha_1)^2/\alpha_0^2\} + B(t)\cos^8(\alpha)$, $\alpha_0 = 36^\circ$, $\alpha_1 = 90^\circ$
- Energy Dependence: Two Electron Populations

Transition range
~ 350-420 keV

- The energy flux of accelerated electrons is 2×10^9 erg / cm²s within an accuracy of $\pm 30\%$ (the uncertainty is associated with the error in determining the loop volume)
- The level of magnetic fluctuations $\delta B/B \ll 10^{-2}$ at $\lambda_B = 10^7$ cm
- Energy density of ion-sound waves $W^s/n_e k_B T_e \ll 10^{-4}$

t=peak

Simulation results

SOL2002:11:10 T 03:11

M2.6

- Two Hard X-ray sources – Northern and Southern in opposite footpoints of the magnetic loop are distinctly allocated.
- Loop length - $L \sim 5.5 \times 10^9 \text{ cm}$. The magnetic field is asymmetric, at the looptop is 66 G, in the southern footpoint - 400 G and 1000 G in the northern footpoint.
- The plasma density at the looptop is $\sim 10^9 \text{ cm}^{-3}$ in the initial flare phase and increases up to $\sim 10^{10} \text{ cm}^{-3}$ in the peak and decay phases as a result of the thermal plasma evaporation.
- Accelerated electrons injected near the looptop in the direction of the southern footpoint at the initial phase. The injection took place in the form of a Gaussian profile with a half-width (FWHM) of 2 Mm.
- The energy flux of the accelerated electrons at the peak $\sim 2 \cdot 10^9 \text{ erg/cm}^2\text{s}$ in the energy range of 30 keV – 10 MeV.

Simulation results

SOL2002:11:10 T 03:11

M2.6

- At the injection site in the peak, the pitch angle distribution of accelerated electrons transformed to anisotropic $S_2(\alpha) = \cos^8(\alpha)$.
- The transition region $E \sim 350-420$ keV is the region of a sharp change in the electron spectrum, separating them, in fact, into two populations. The energy spectral index of accelerated electrons up to the transition region δ_1 is variable, varying in time from 4.5 to 2.8 at the peak and up to 4 at the decay (SHS). At the peak, power-law index of the accelerated electrons after the transition region $\delta_2 = 2-2.3$.
- The average number density of accelerated electrons, mainly responsible for radiation at 17 GHz and 34 GHz, is $n_b \sim 3 \times 10^3 \text{ cm}^{-3}$ ($E > 350$ keV).
- The average number density of the accelerated electrons in the range 30keV-10MeV n_b is $\sim 10^7 \text{ cm}^{-3}$ in the region of the radio source 17GHz and $n_b \sim 2 \cdot 10^5 \text{ cm}^{-3}$ in the Hard X-ray source in the southern part of the magnetic loop.
