

# *Condensate and Quasiparticle Transport in a Bilayer Quantum Hall Excitonic Superfluid*

*Jim Eisenstein*

Aaron Finck

Debaleena Nandi

Loren Pfeiffer

Ken West

U.S. DEPARTMENT OF ENERGY: BASIC ENERGY SCIENCE

*Division of Materials Sciences*

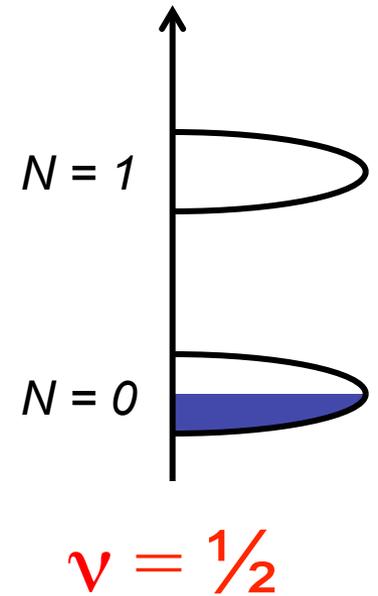

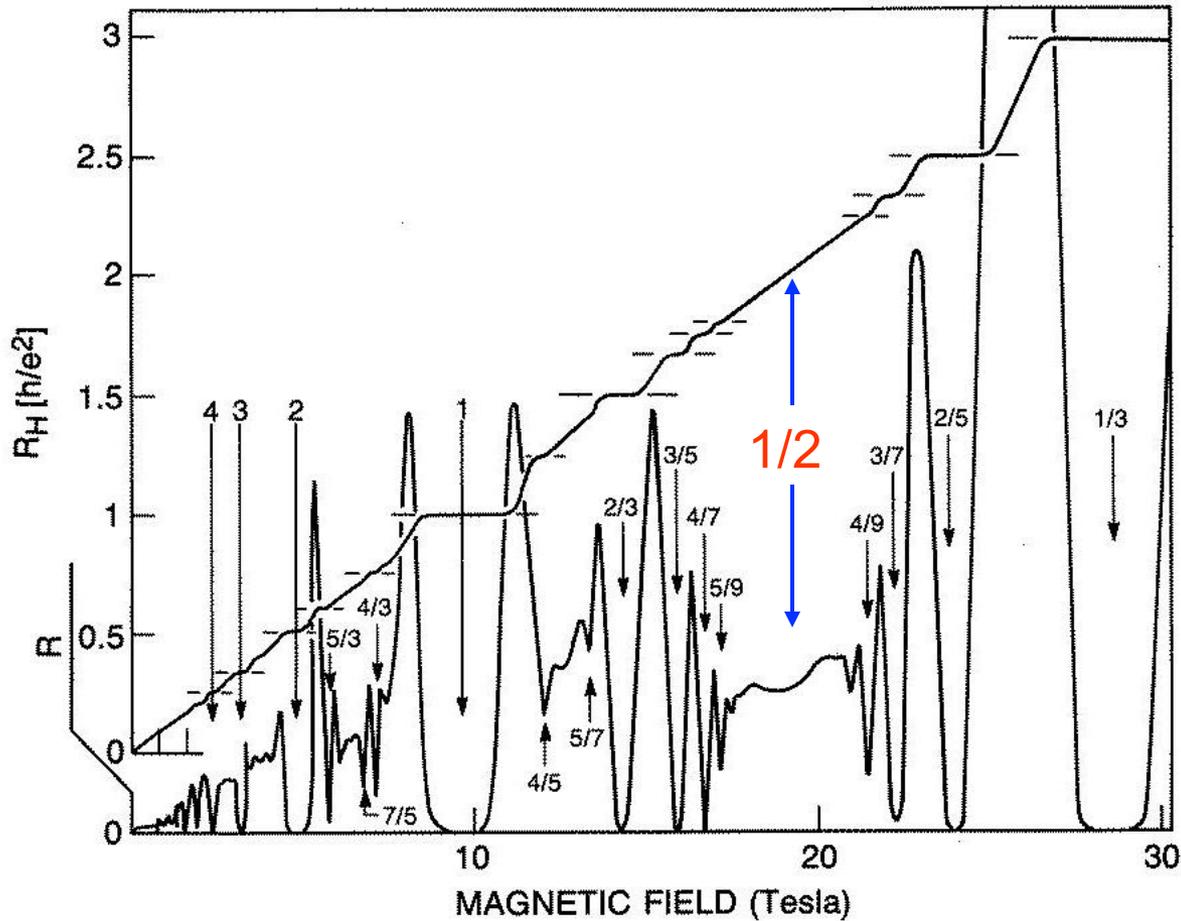

*ISSO-2012 St. Petersburg, July 2012*

## *Outline of the talk*

1. QHE & phase transition at  $\nu_T = 1$
2. nature of the condensed phase
3. counterflow transport in Hall bars
4. pause...
5. counterflow transport in Corbino rings
6. perfect and imperfect Coulomb drag
7. dissipation in counterflow

phase transition

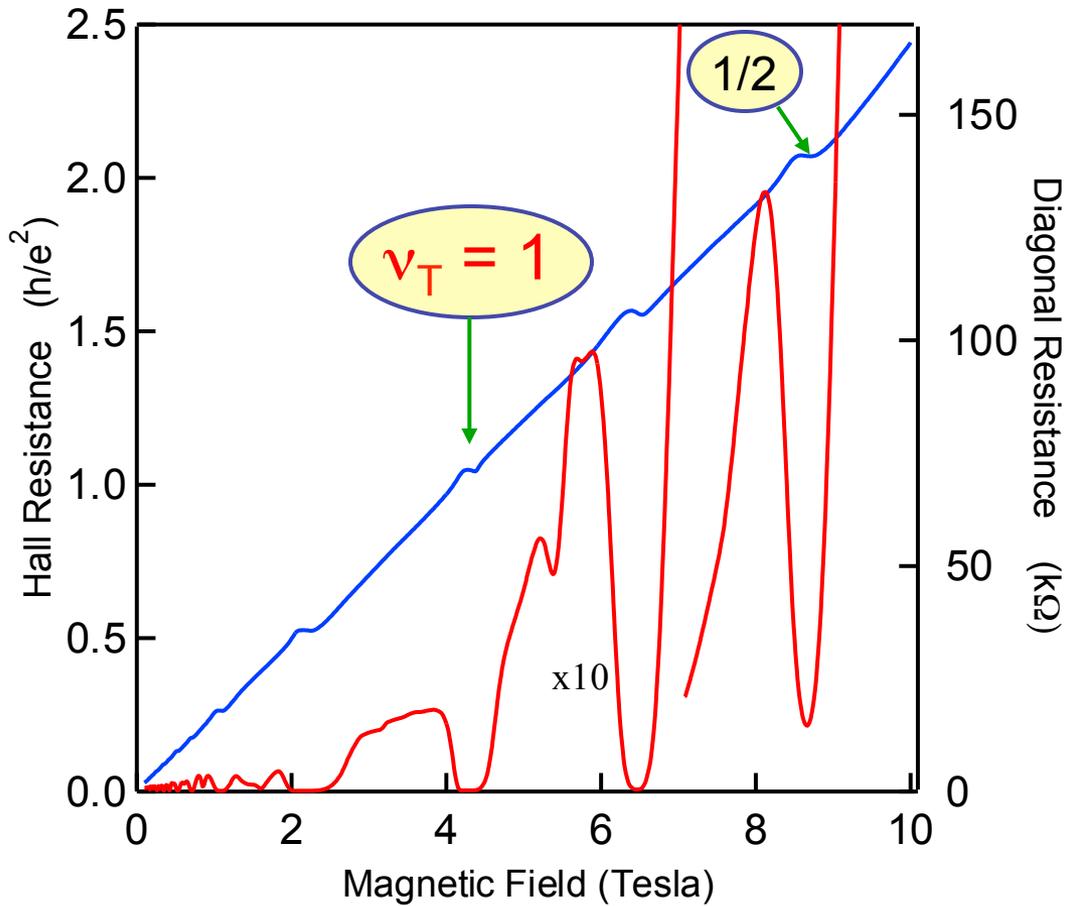

# Quantum Hall Effect in a Single Layer 2D System

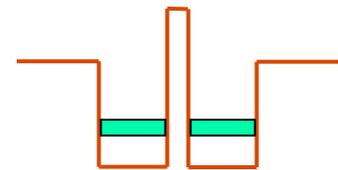

No QHE at half-filling of the lowest Landau level

# QHE in Double Layer 2D Systems

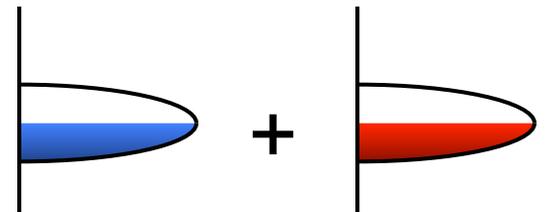

$$\nu_T = \nu_1 + \nu_2$$

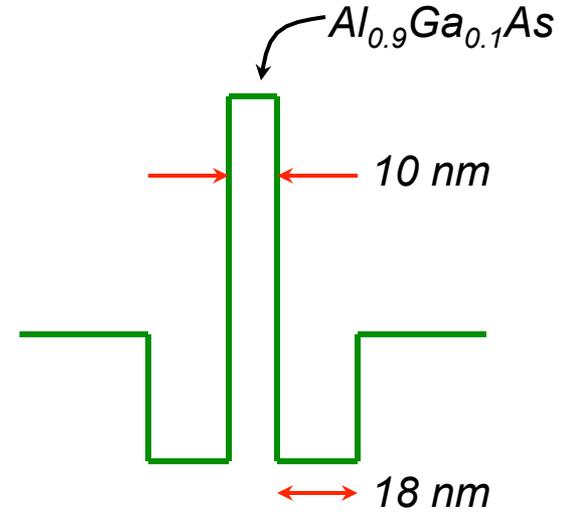

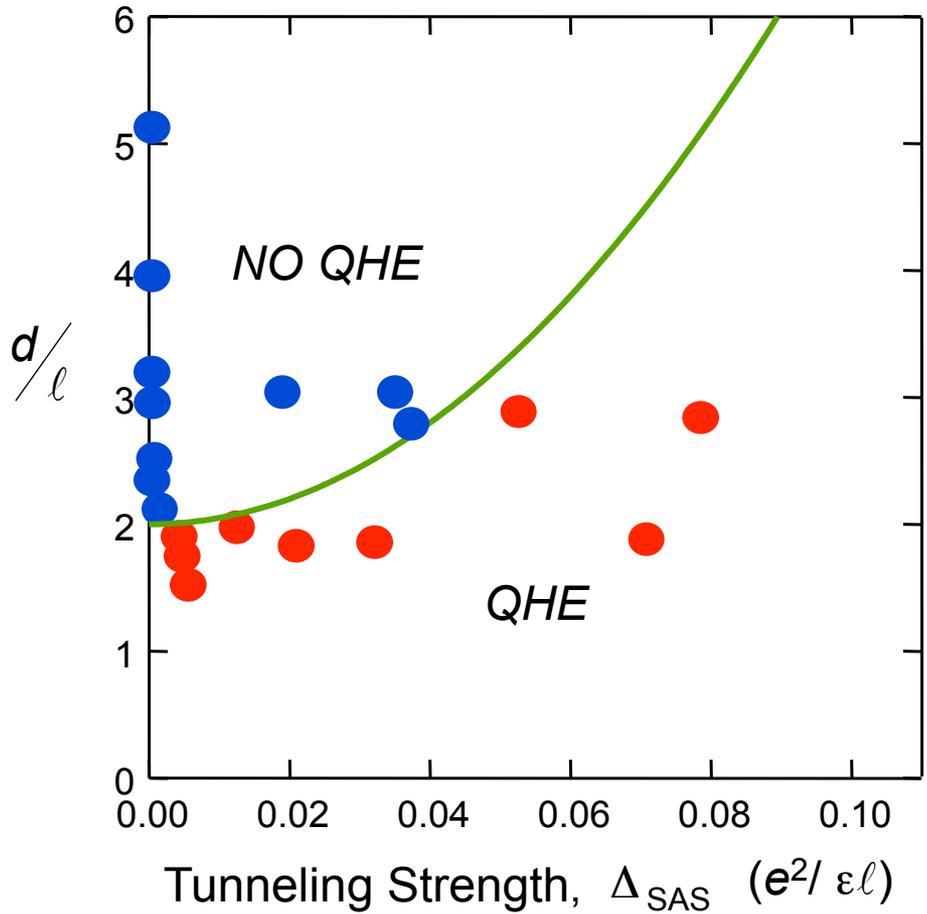

$$\nu_T = 1/2 = 1/4 + 1/4$$

$$\nu_T = 1 = 1/2 + 1/2$$

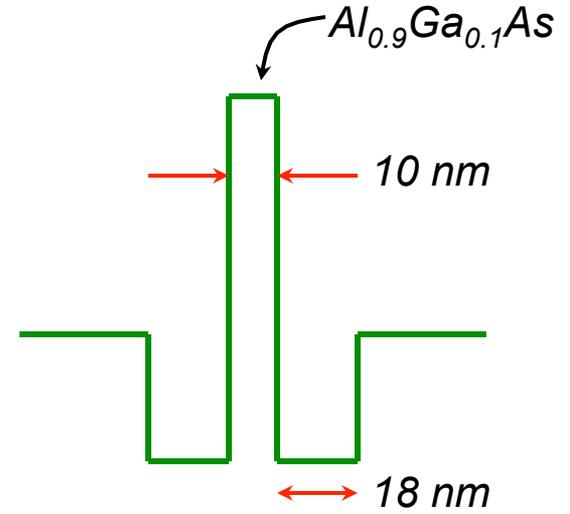

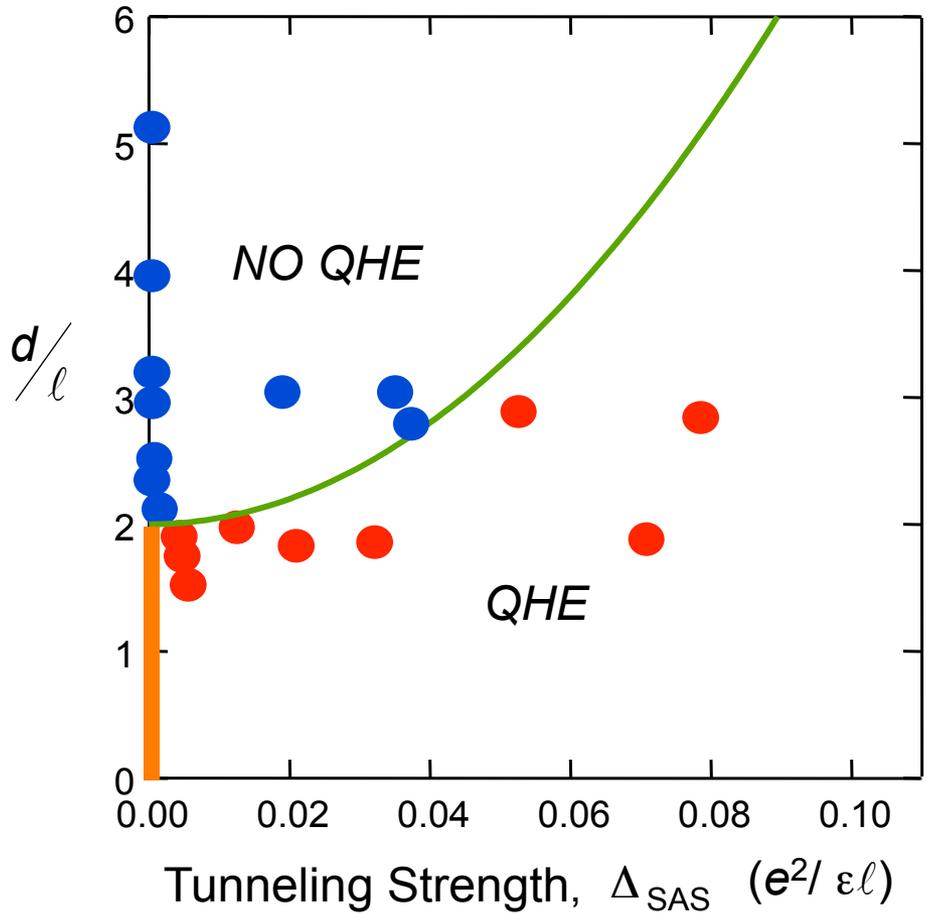

# Phase Diagram at $\nu_T = 1$

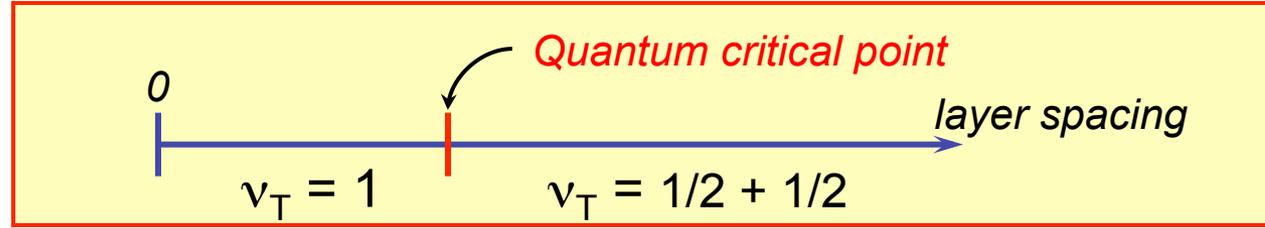

Continuous evolution of QHE

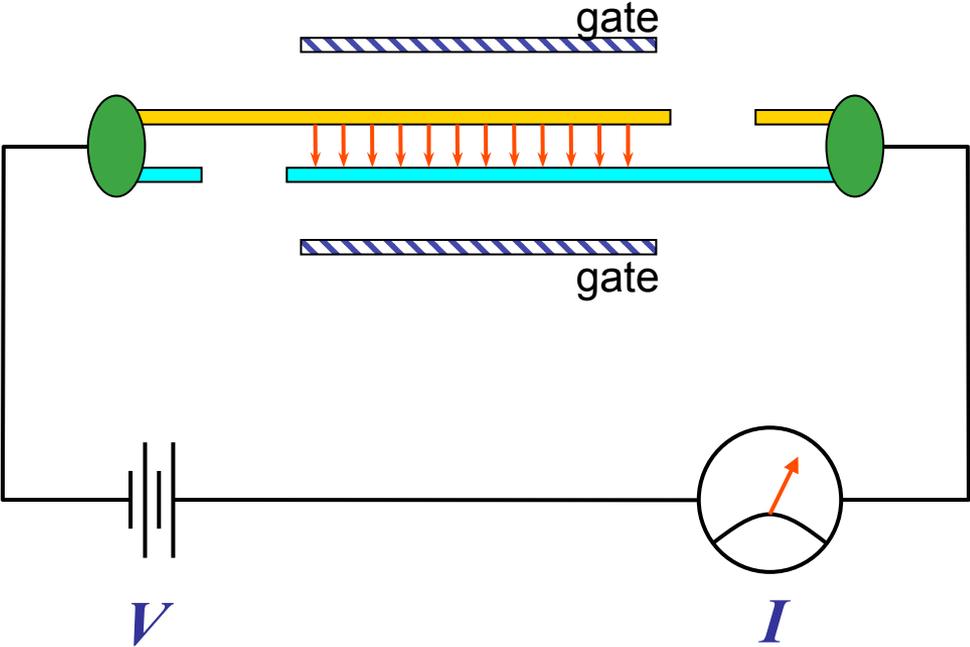

# Phase Diagram at $\nu_T = 1$

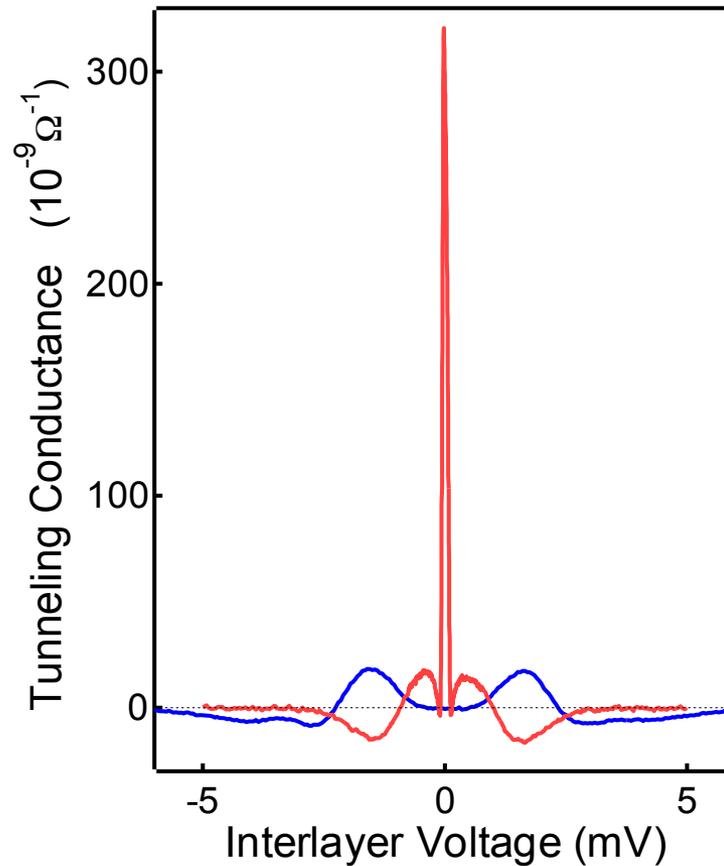

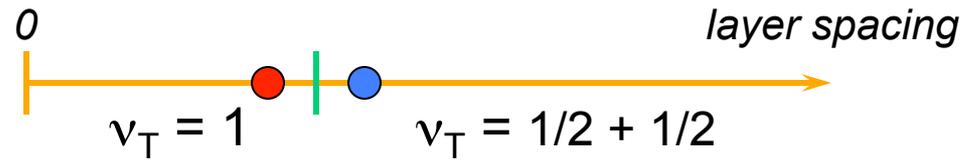

$\Delta_{SAS} \sim 10 \mu K \sim 10^{-7} e^2/\epsilon l$   
*Extreme Coulomb limit*

*Tunneling signature of transition*

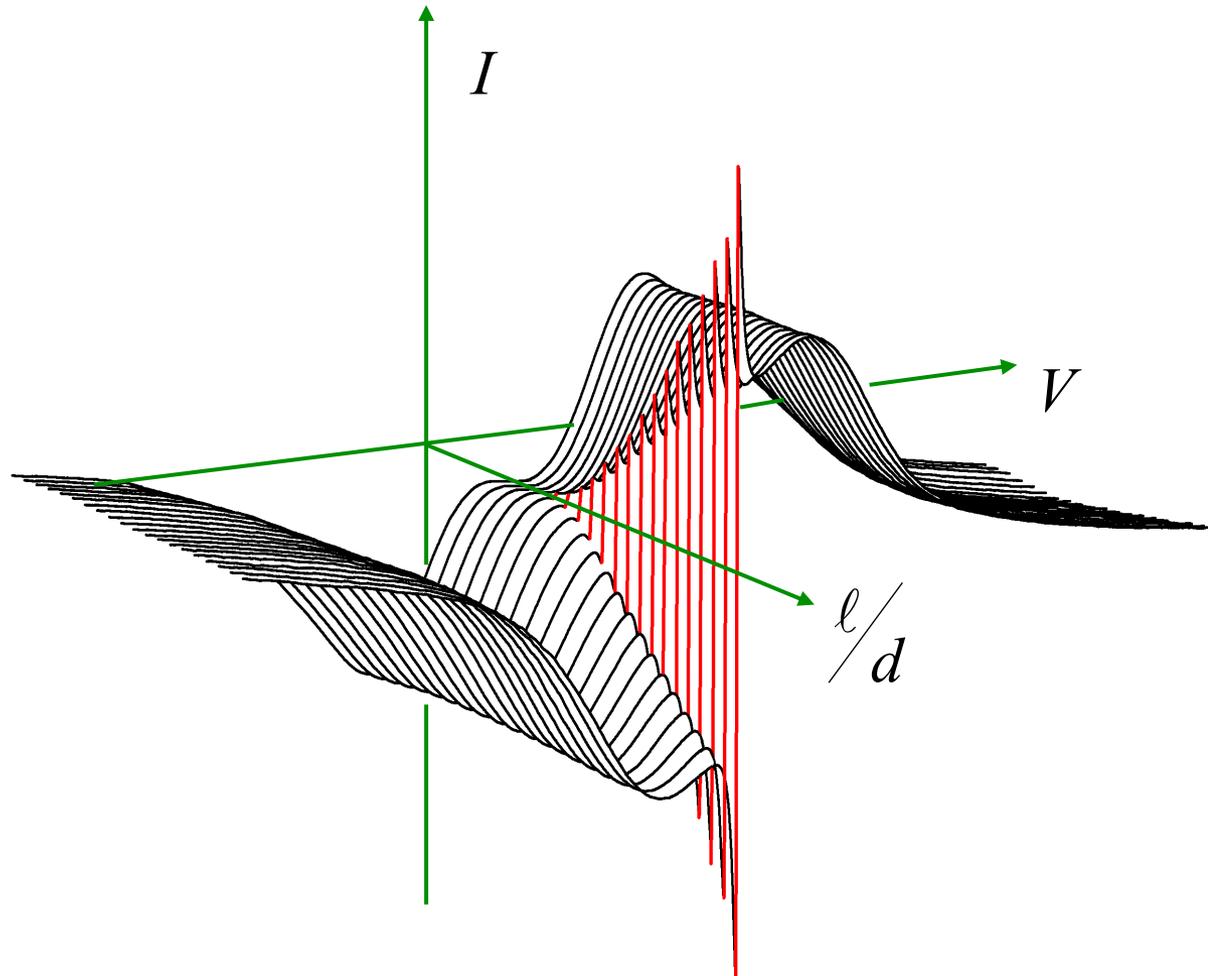

## Tunneling signature of transition

*Coulomb gap replaced by resonant enhancement.*

## Josephson-like tunneling I-V

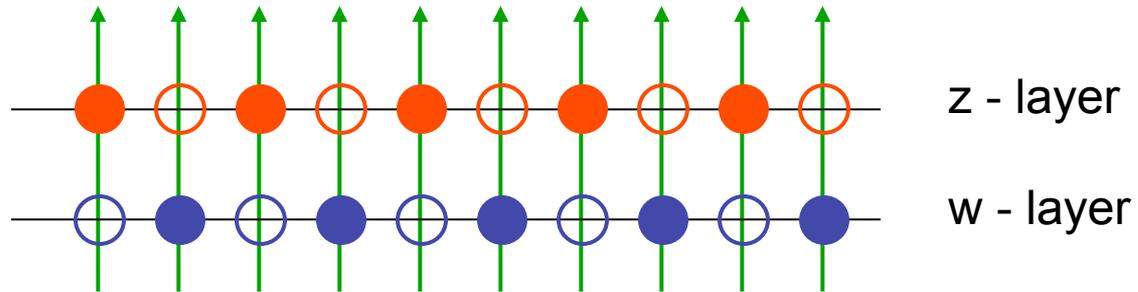

Onset coincident with appearance of QHE.

nature of the condensed phase

## Halperin 111 state

Pure many-body effect

$$\Psi \sim \prod_{i, \dots, n} (z_i - z_j) (w_k - w_l) (z_m - w_n)$$

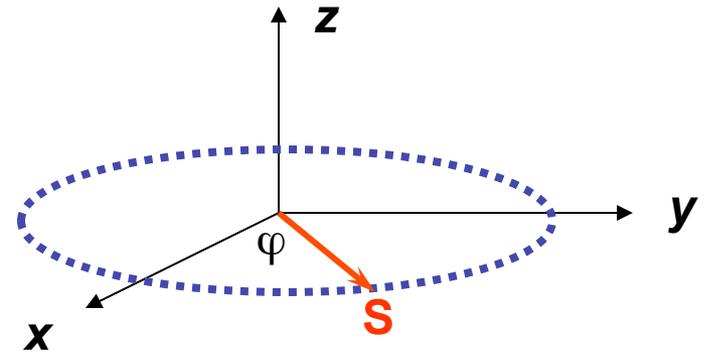

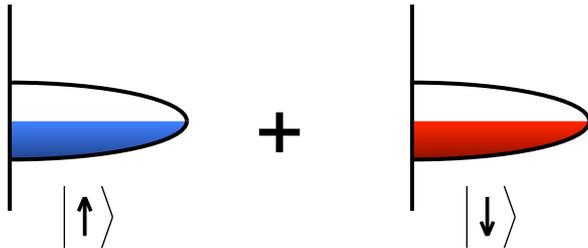

Laughlin-like intra- and inter-layer correlations

*Essentially exact in the  $d/\ell \rightarrow 0$  limit.*

# Easy-Plane Ferromagnet

layer index  $\rightarrow$  *pseudospin*

$$|\Psi\rangle = \prod_k |k\rangle \otimes \left( |\uparrow\rangle + e^{i\varphi} |\downarrow\rangle \right)$$

Exchange-driven “spontaneous interlayer phase coherence”

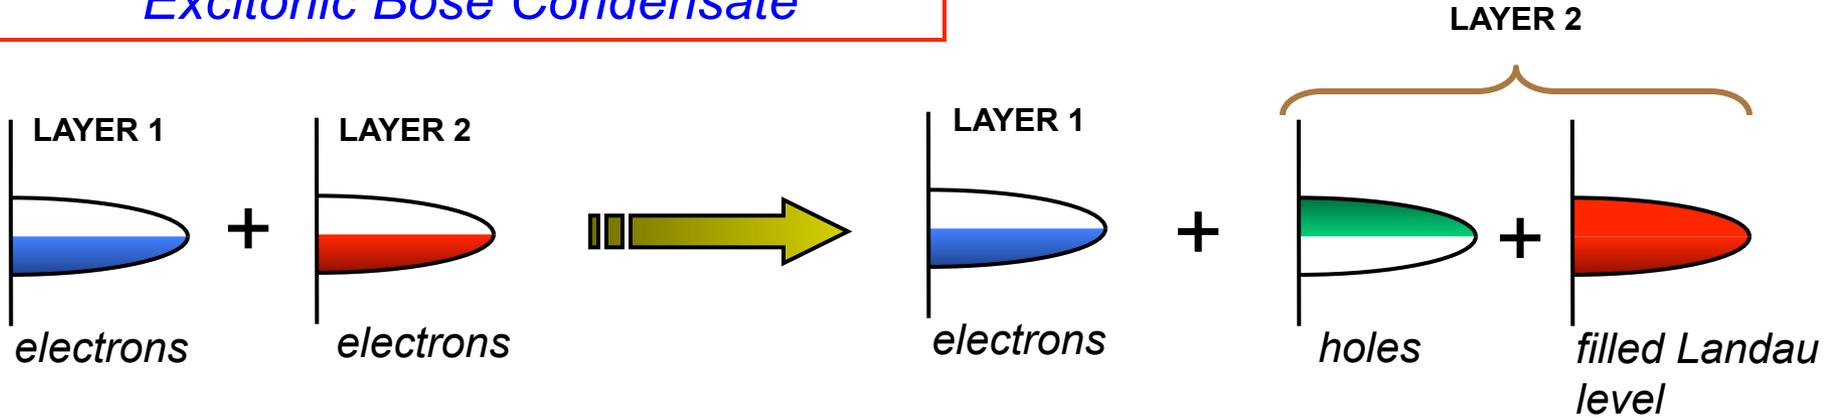

*pseudospin waves (Goldstone modes)*

*charged vortices*

*Kosterlitz-Thouless transition*

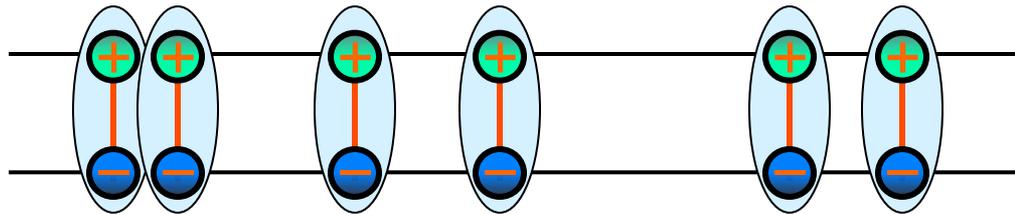

# Excitonic Bose Condensate

$$|\Psi\rangle = \prod_k \frac{1}{\sqrt{2}} \left[ 1 + \underbrace{e^{i\phi} c_{k,1}^\dagger c_{k,2}}_{\text{exciton creation operator}} \right] |vac'\rangle$$

exciton creation operator

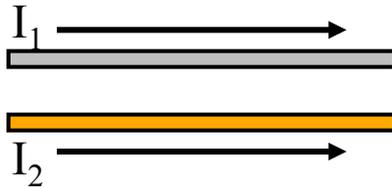

$\nabla\phi$   $\longrightarrow$  excitonic supercurrents

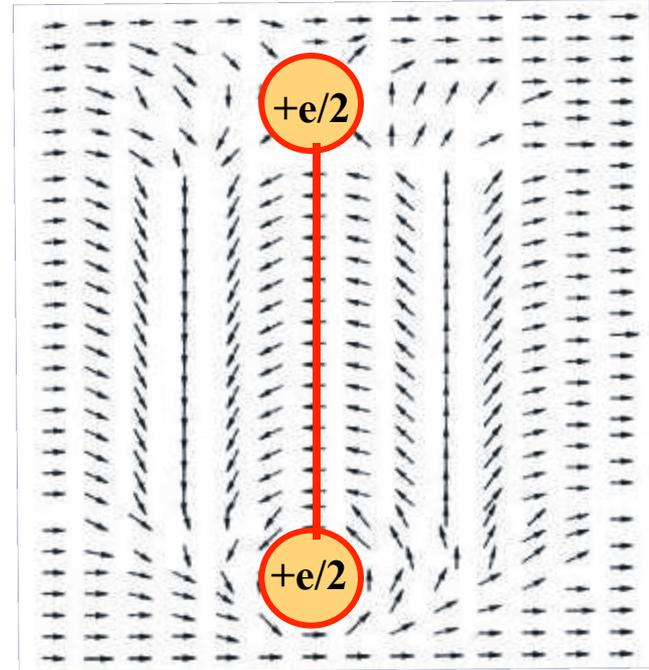

# Two Transport Channels

## 1. Parallel Transport

*meron / anti-meron pair*

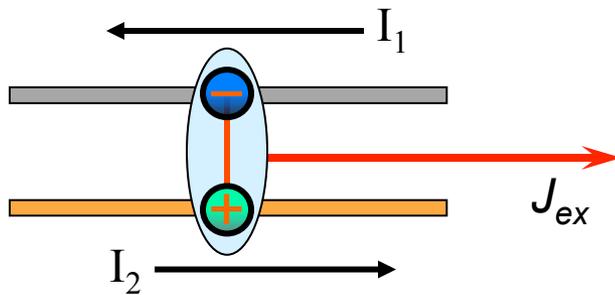

*quantized Hall effect*

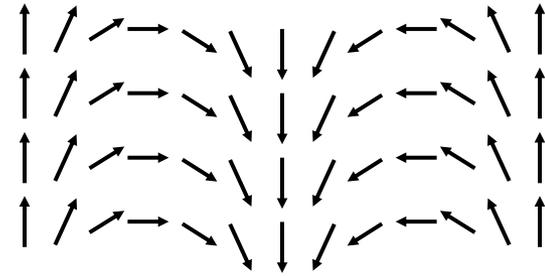

# Two Transport Channels

## 2. Counterflow Transport

$$\nabla\phi = \text{constant}$$

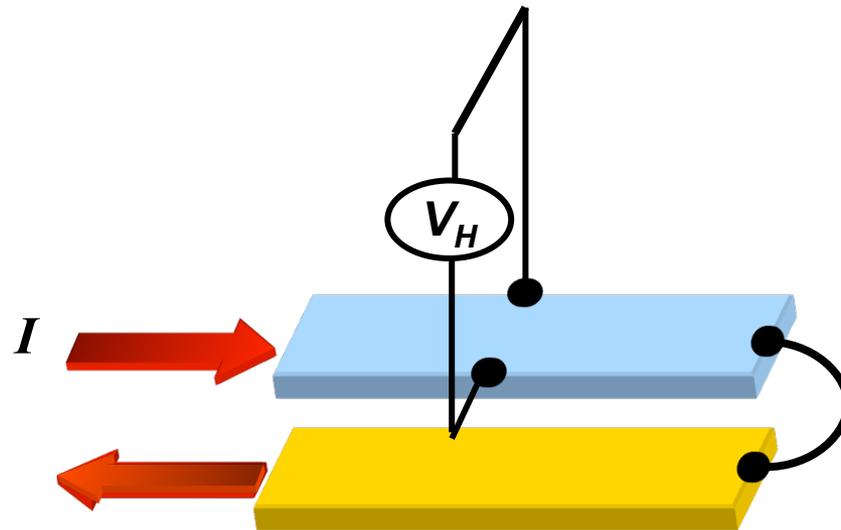

$$J_{ex} = \rho_s \nabla\phi$$

collective exciton transport in condensate

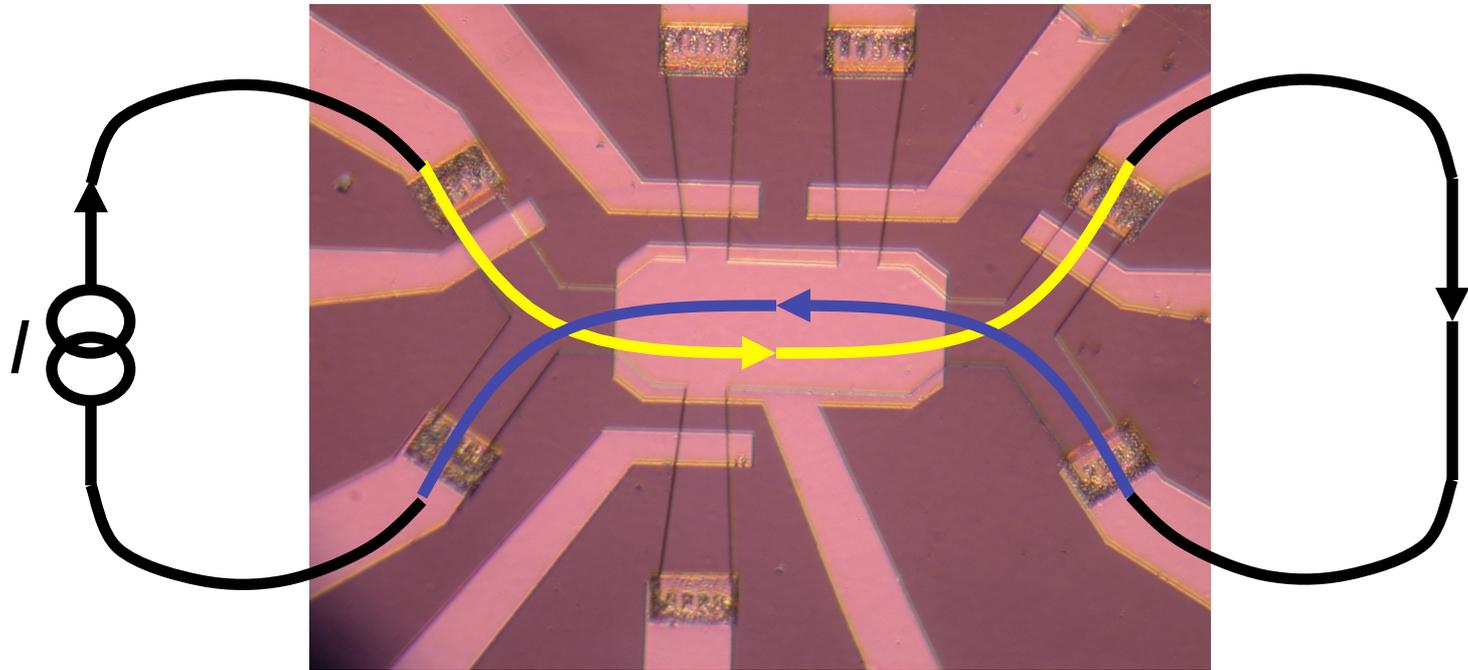

counterflow in Hall bars

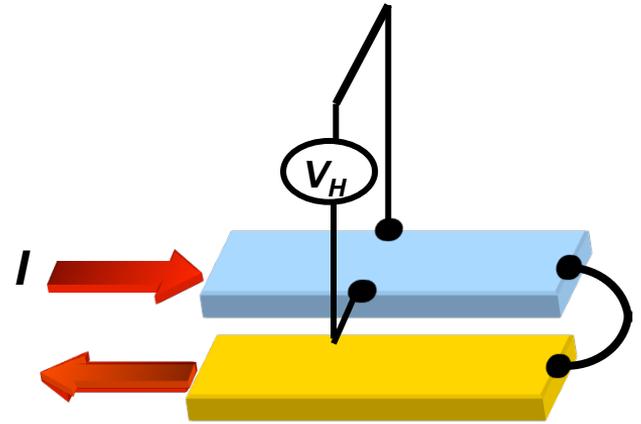

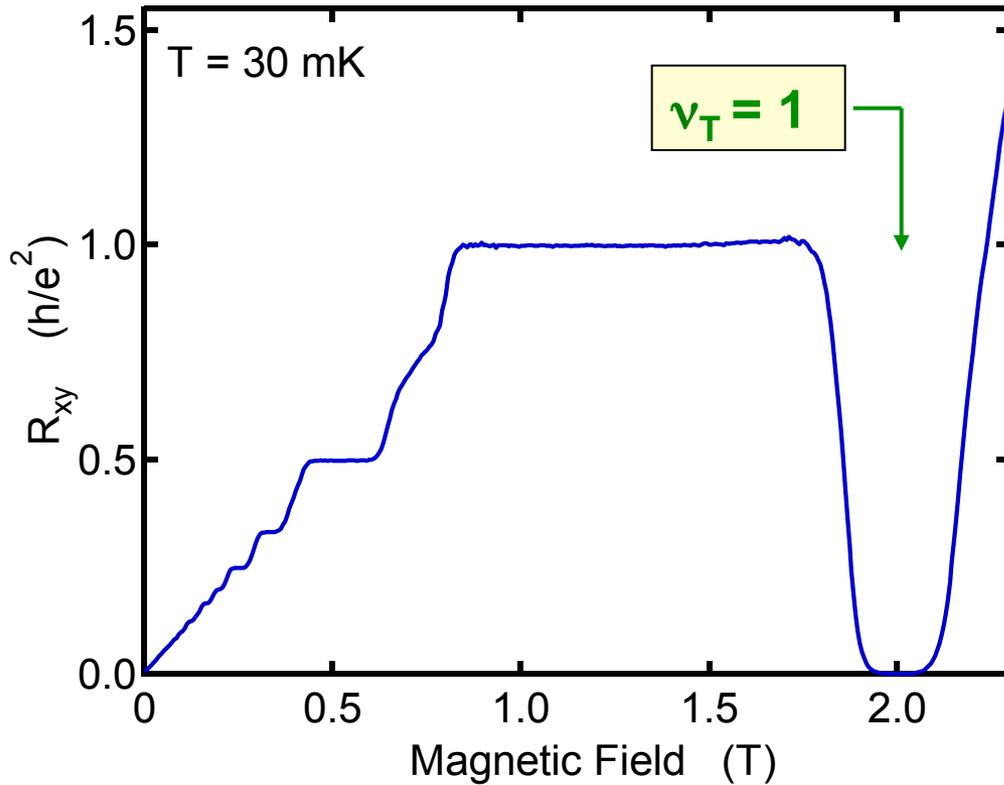

# Counterflow Experiment

# Counterflow Experiment

## Counterflow Experiment

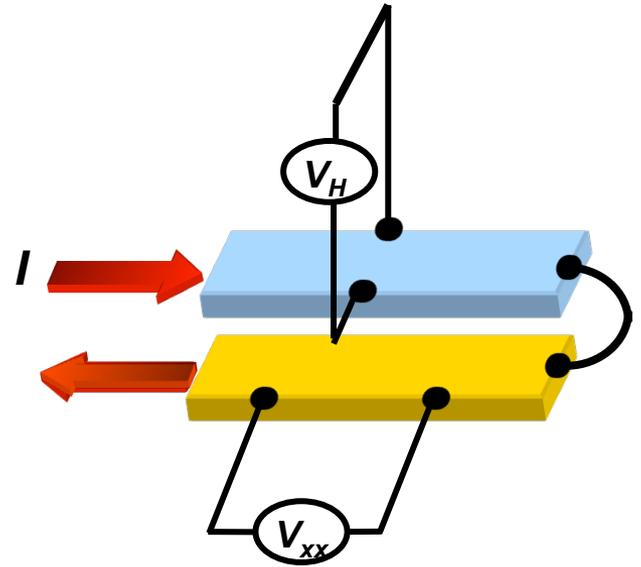

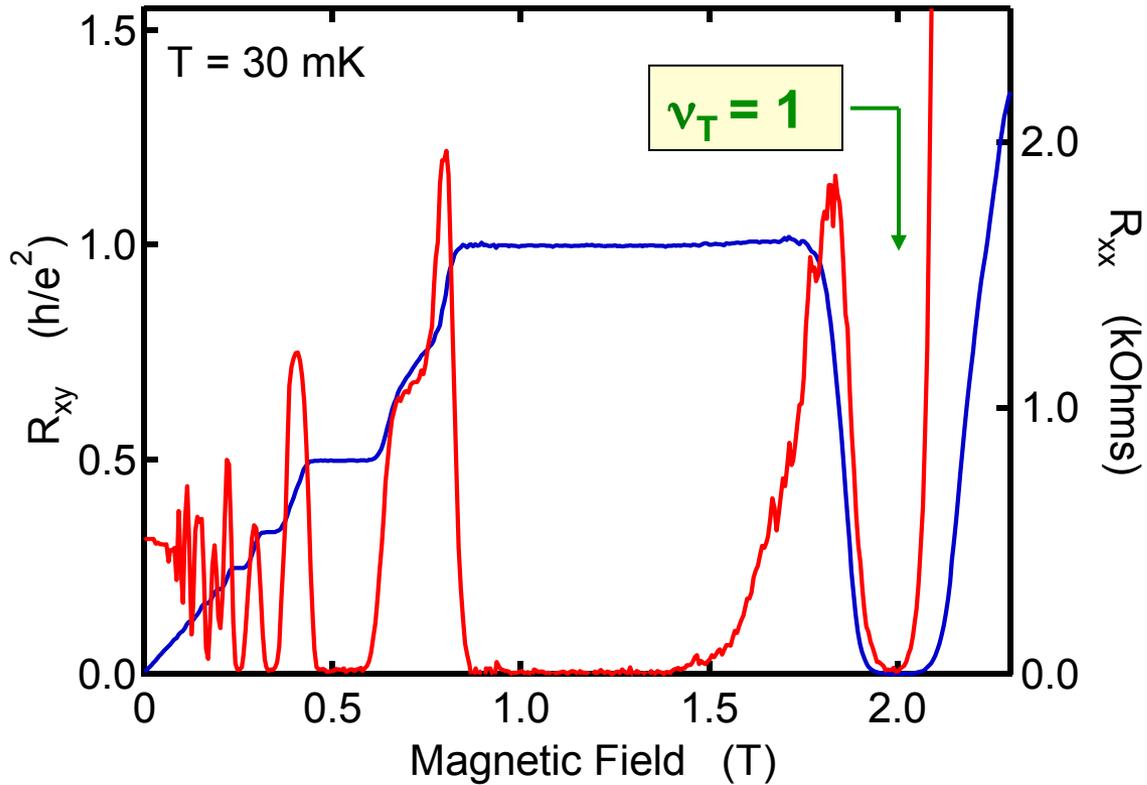

Kellogg 2004  
Tutuc 2004

At  $\nu_T = 1$   $R_{xy}^{CF} \rightarrow 0$  as  $T \rightarrow 0$   $\longrightarrow$  exciton transport

## Counterflow Experiment

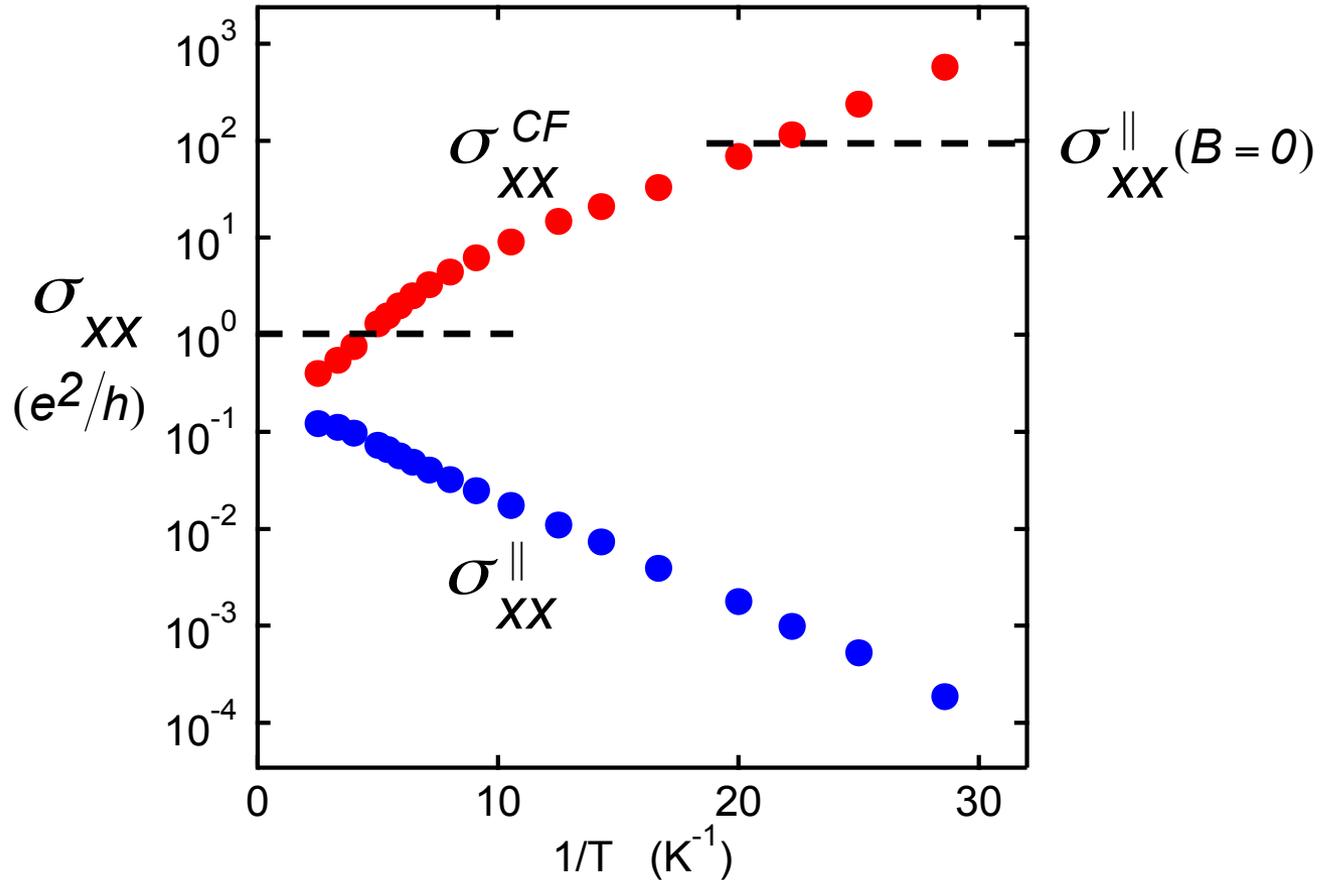

At  $\nu_T = 1$ :  $R_{xy}^{CF} \rightarrow 0$  and  $R_{xx}^{CF} \rightarrow 0$

*Excitonic superfluidity?*

## Counterflow Experiment

$d/\ell = 1.5$

Counterflow dissipation small but non-zero at all finite  $T$ .

*Pause and reflect...*

1. phase transition
2. QHE
3. tunneling anomaly
4. Goldstone modes (pseudospin waves)
5. quantized Hall drag
6. counterflow transport
7. etc.

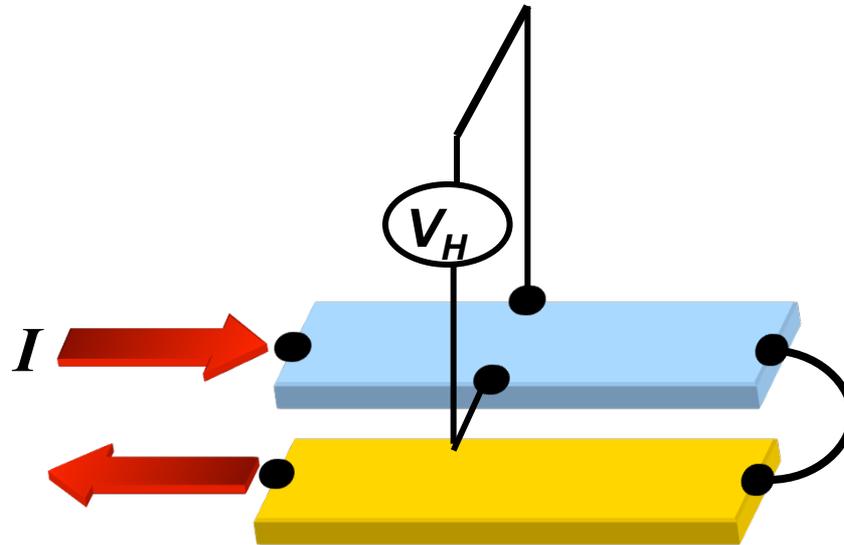

*Qualitatively, theory = experiment*

*Pause and reflect...*

1. phase transition
2. QHE
3. tunneling anomaly
4. Goldstone modes (pseudospin waves)
5. quantized Hall drag
6. counterflow transport
7. etc.

*Qualitatively, theory = experiment,  
but  
deep questions remain.*

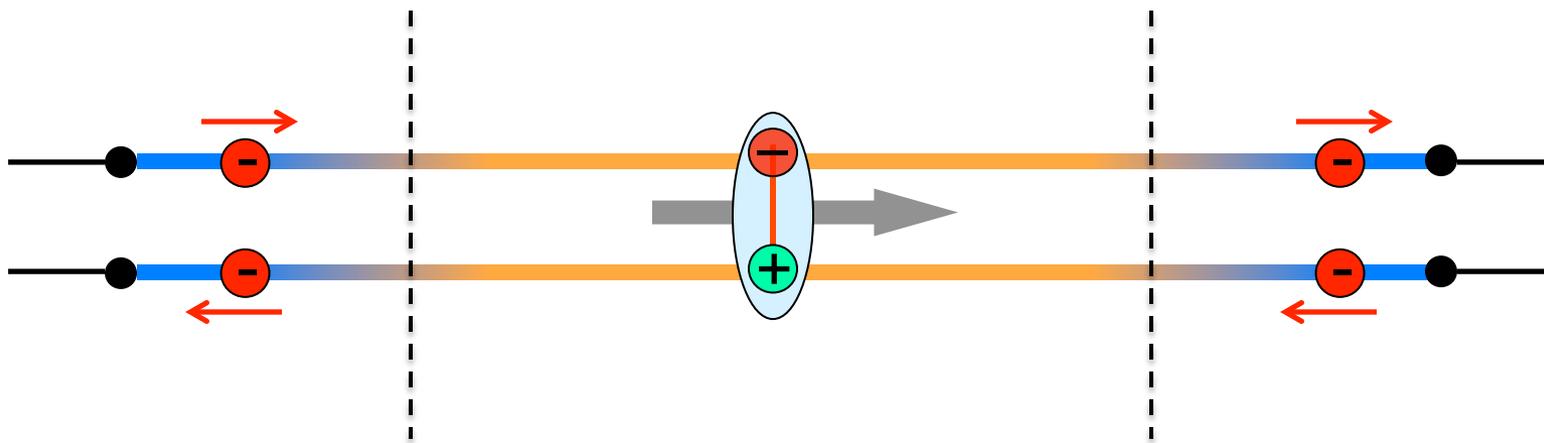

## Counterflow Experiment

*What is really going on?*

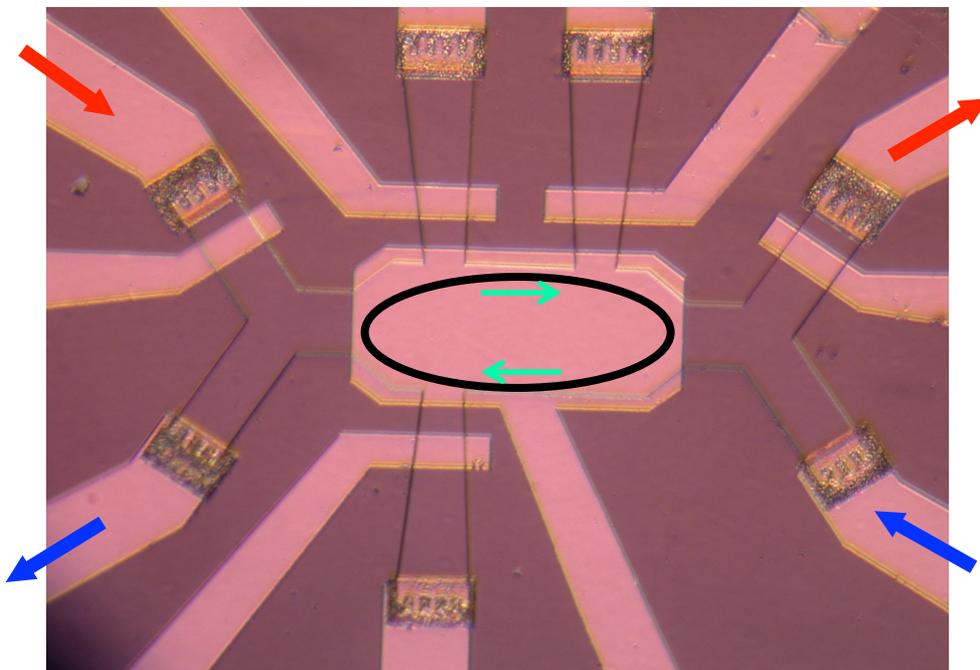

## Counterflow Experiment

Andreev reflection and exciton transport?

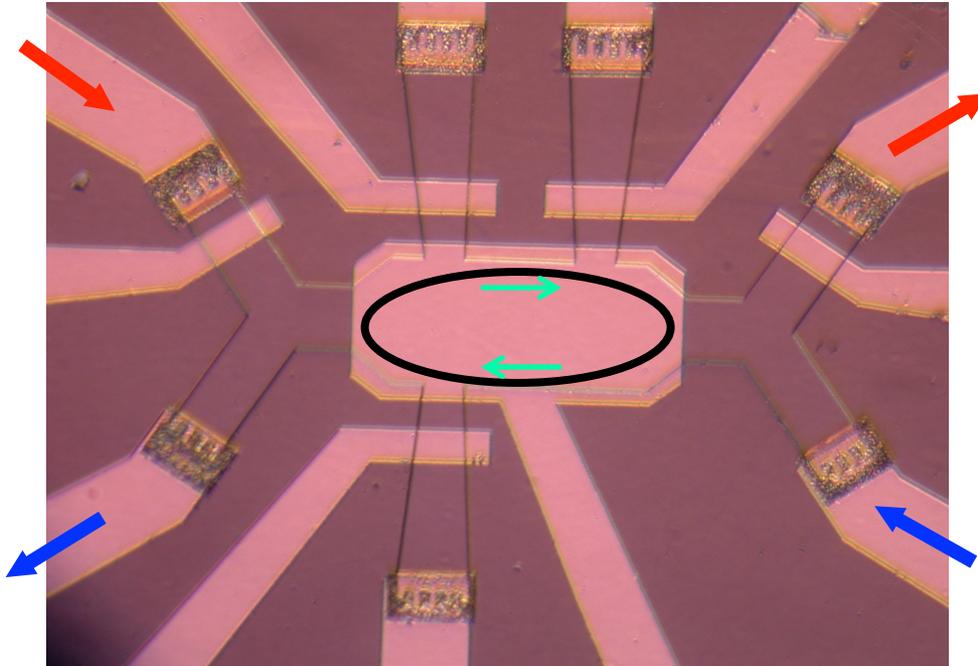

## Counterflow Experiment

What role does the  $\nu = 1$  edge state play?

## Counterflow Experiment

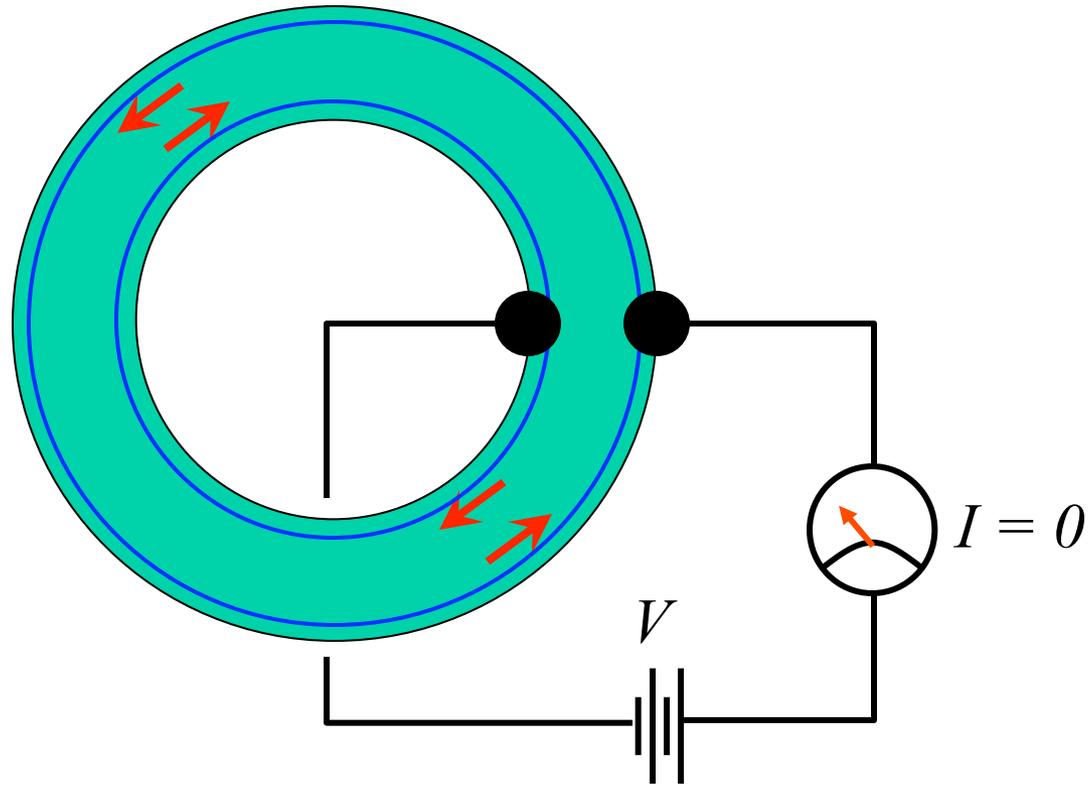

*Experiments on simply connected Hall bars cannot directly demonstrate bulk exciton transport.*

counterflow in Corbino rings

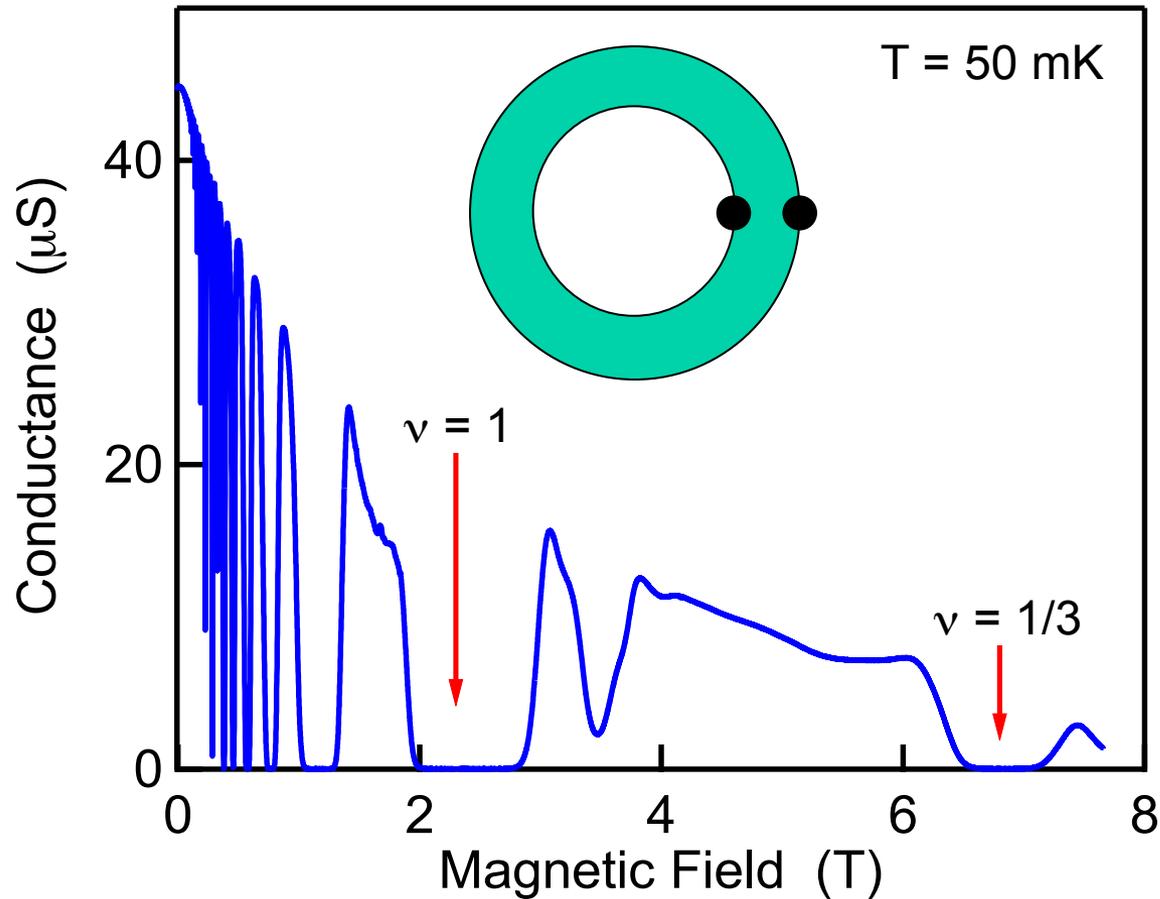

*Quantum Hall systems are topological insulators*

*Contacts on different edges are isolated.*

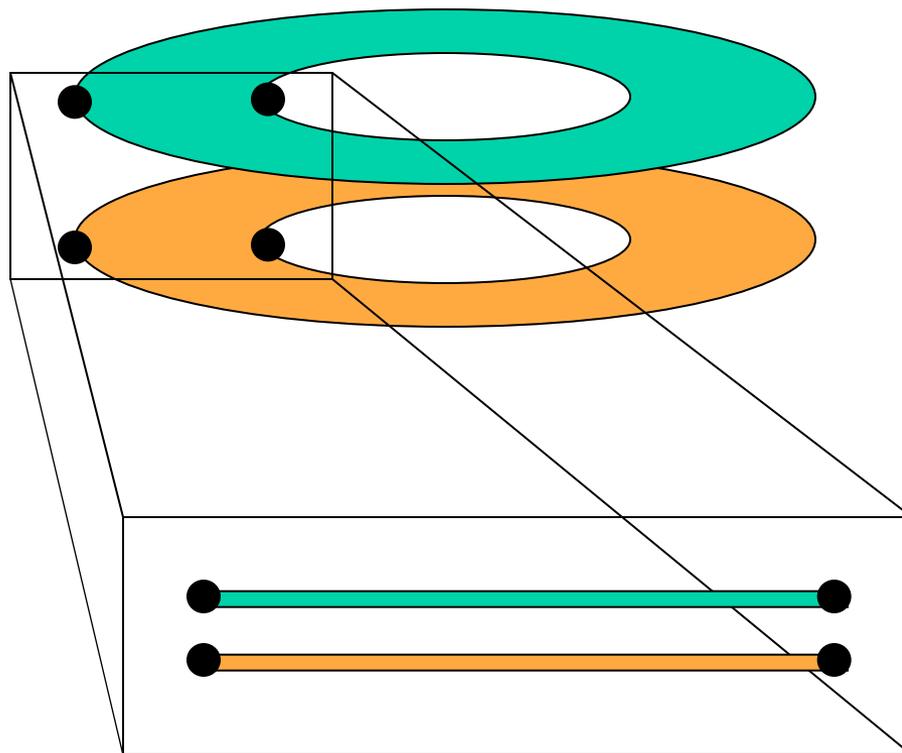

*Corbino geometry measures bulk conductivity*

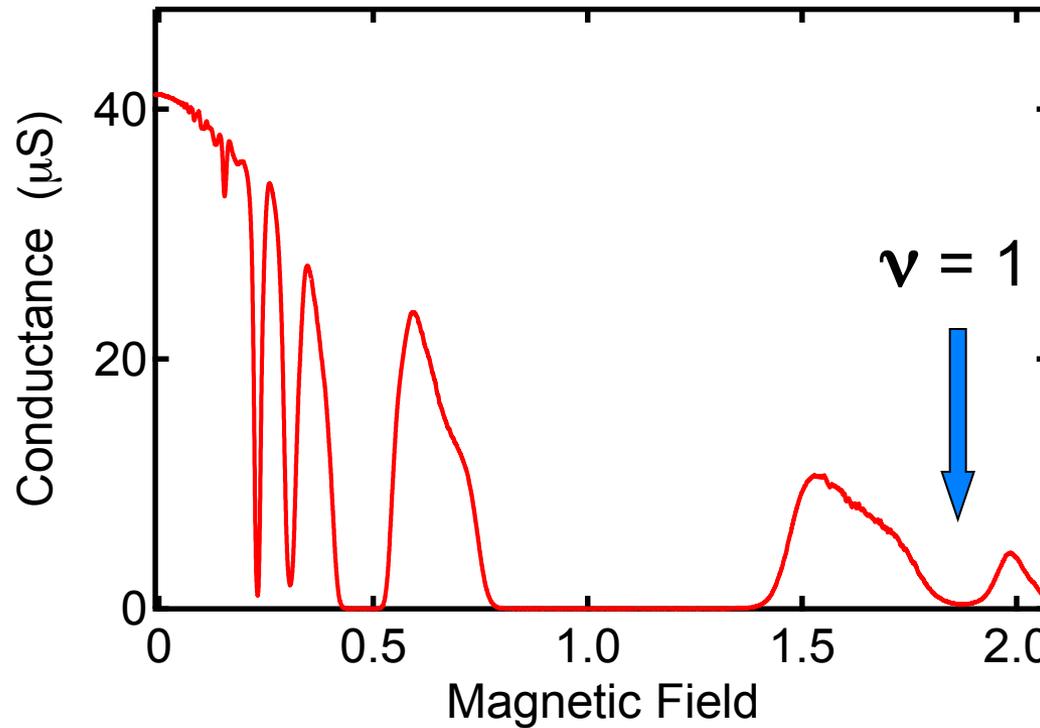

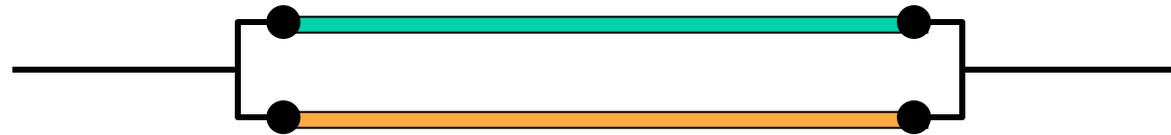

*Bulk conductivity vanishes when QHE is well-developed.*

# Corbino Experiments

*QHE suppresses parallel charge transport across the bulk*

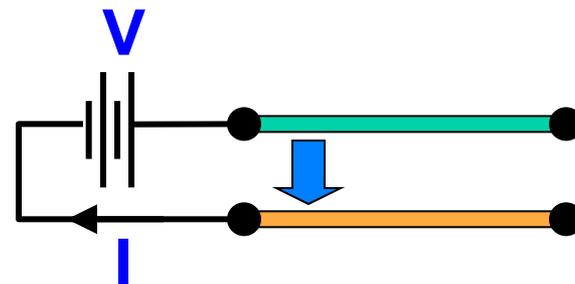

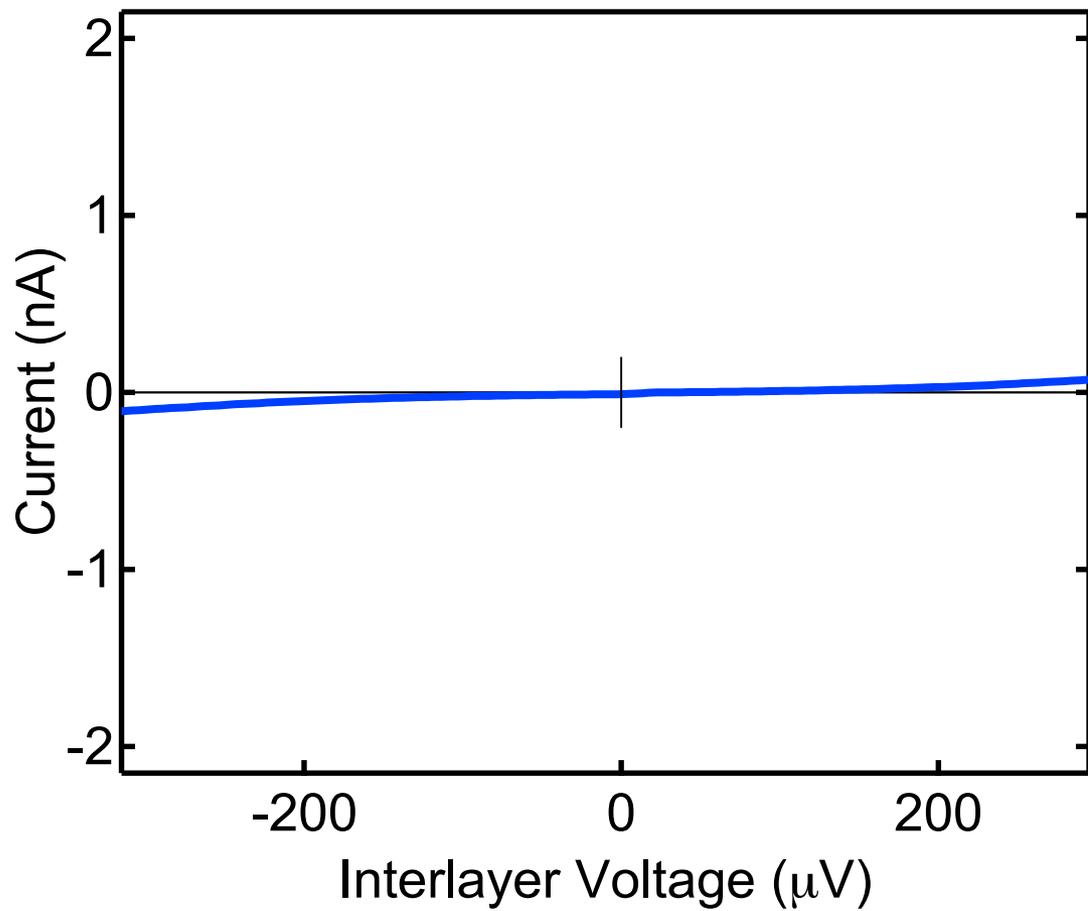

$T = 25 \text{ mK}$

$d/l = 1.5$

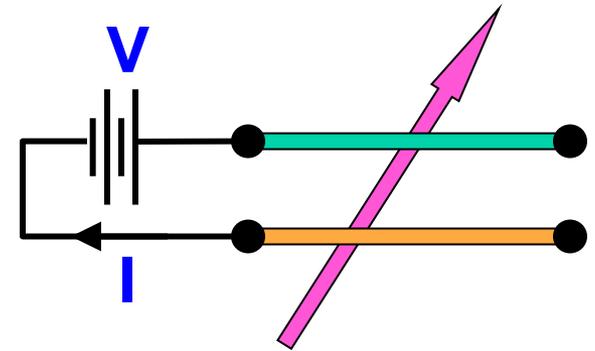

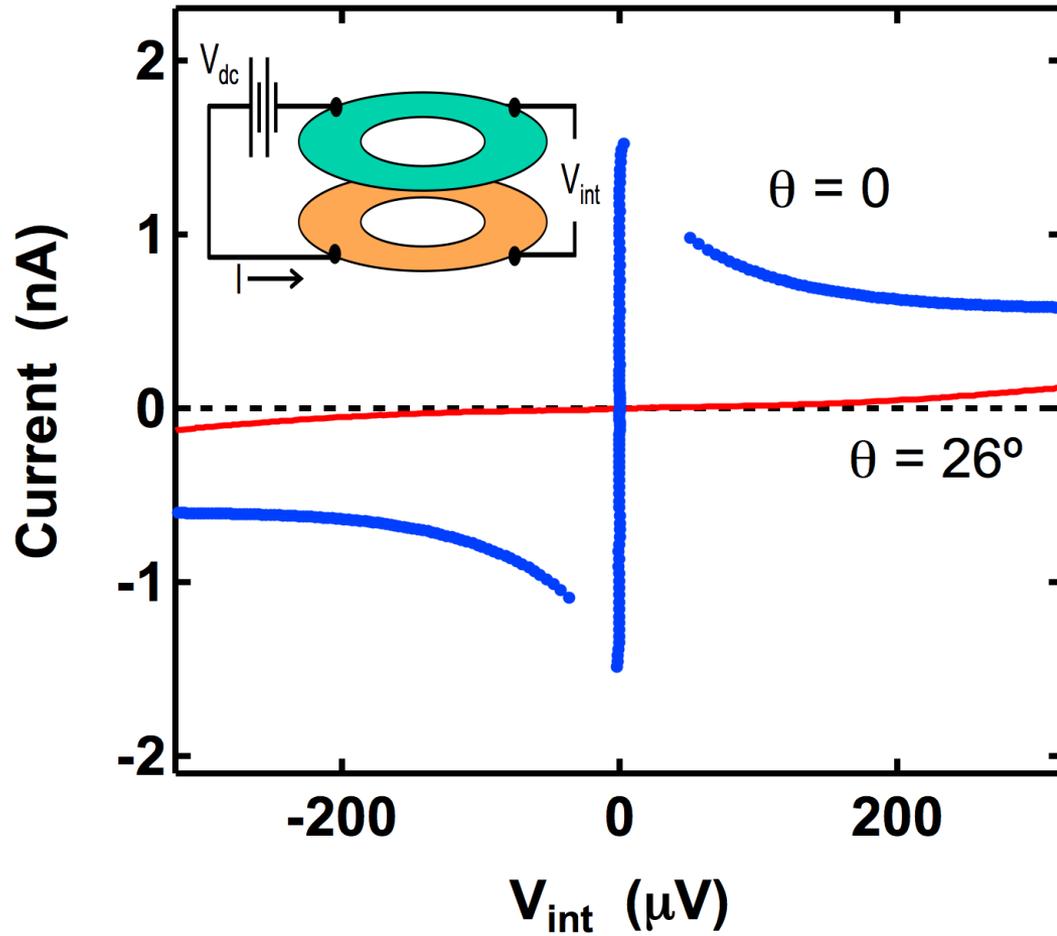

*No surprise here.*

# Tunneling configuration

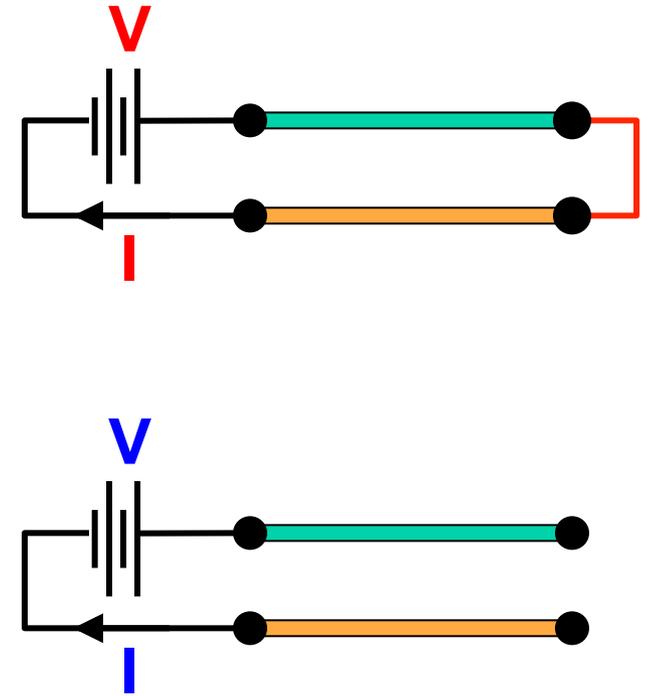

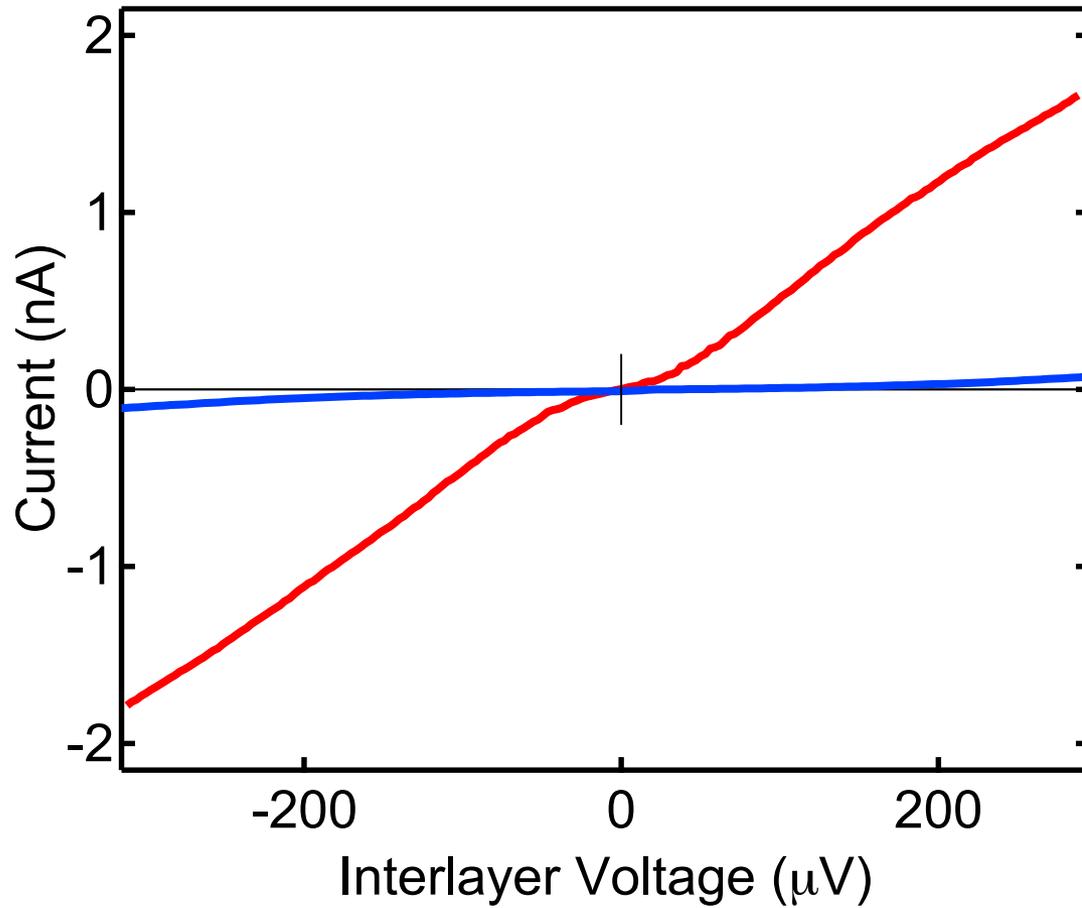

# Tunneling configuration

Tunneling intentionally suppressed by tilting.

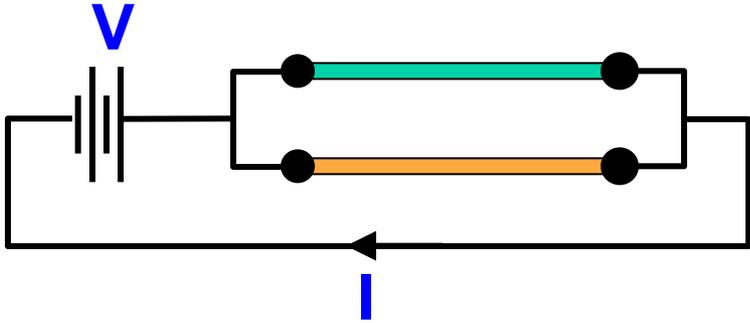

*Tunneling vs. Corbino counterflow*

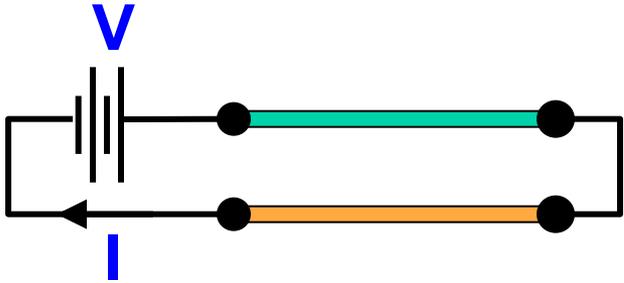

*Remote short vastly enhances current.*

*A Paradox?*

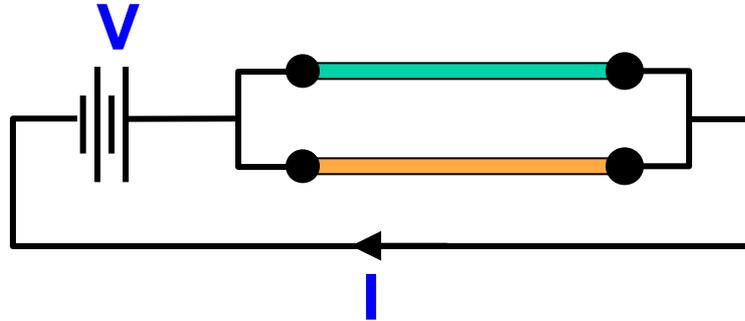

No current

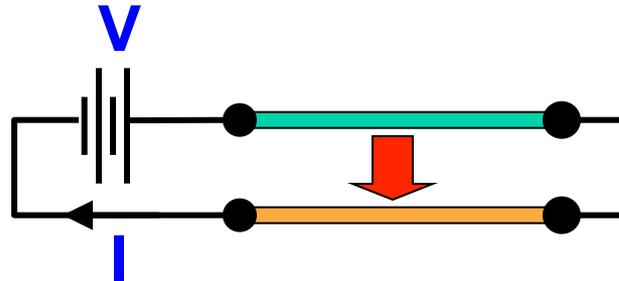

Lots of current

*How can it be?*

No current

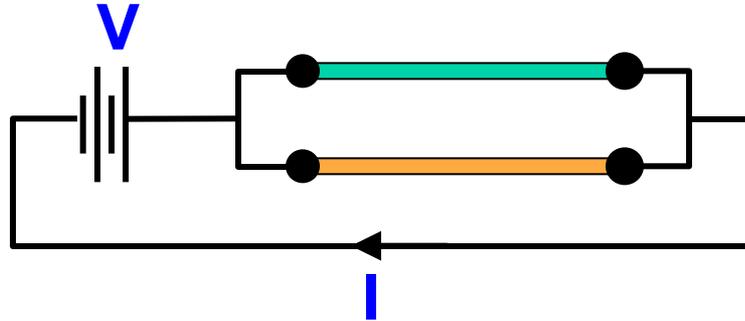

Lots of current

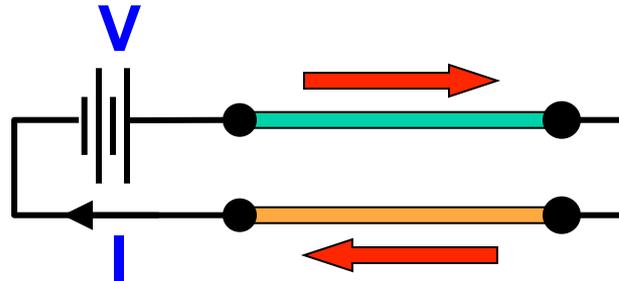

*Enhanced tunneling?*

How can it be?

No current

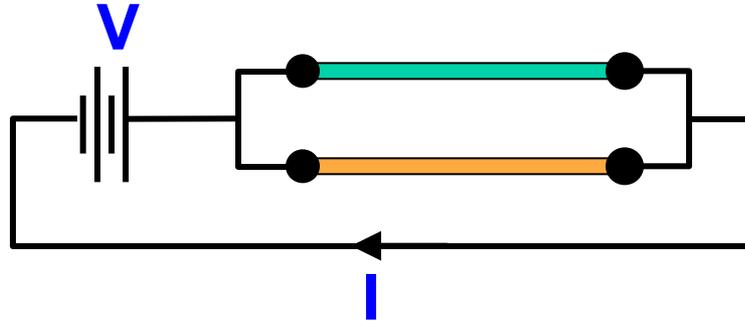

Lots of current

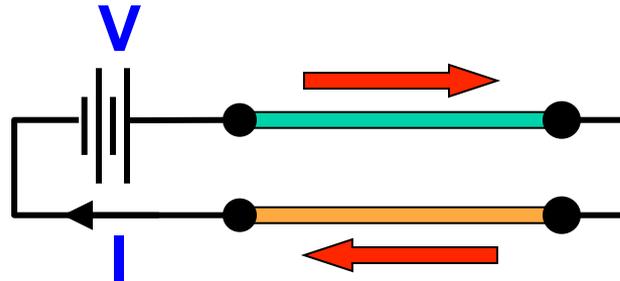

Counterflow?

How can it be?

No current

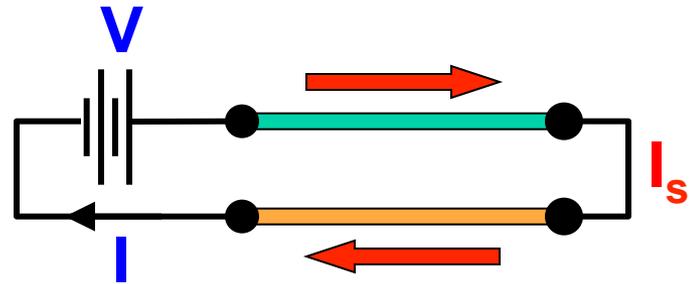

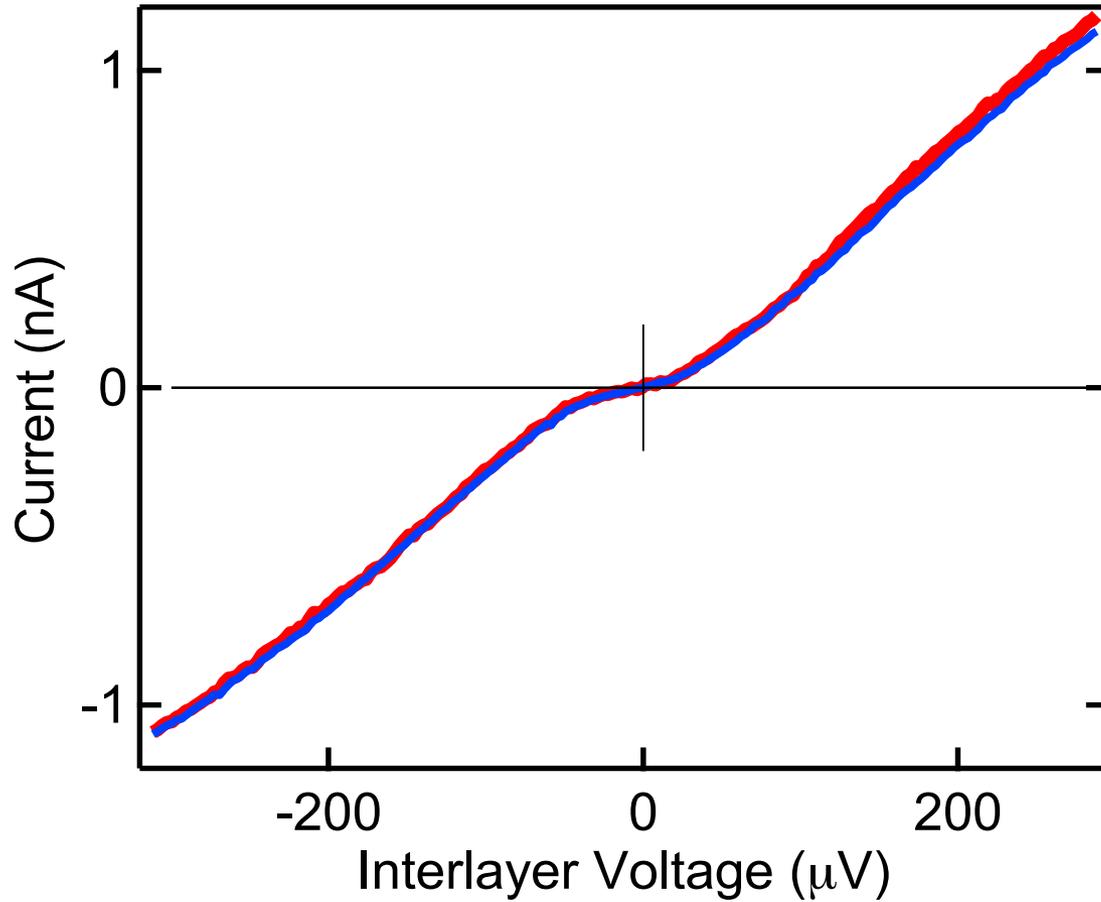

Lots of current

Counterflow?

Measure current here!

## Measuring the shunt current

*It IS counterflow.*

*What we now know...*

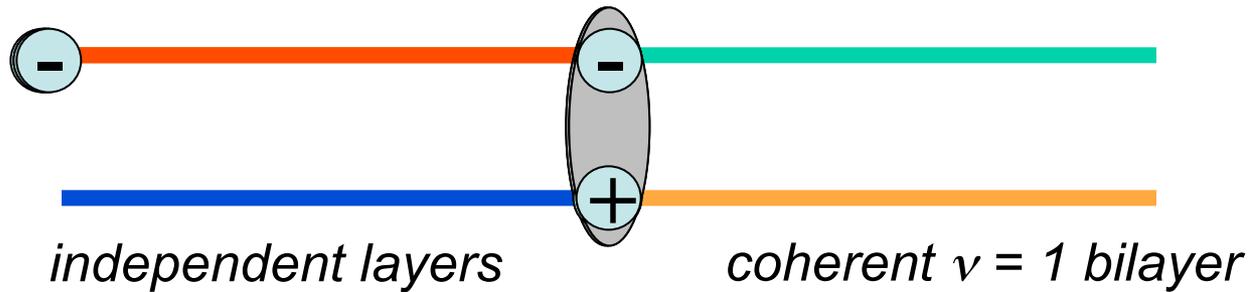

Counterflowing electrical currents can cross the insulating bulk;  
parallel currents cannot.

Counterflow is an intrinsically bilayer phenomenon.

*Counterflow **IS** exciton transport.*

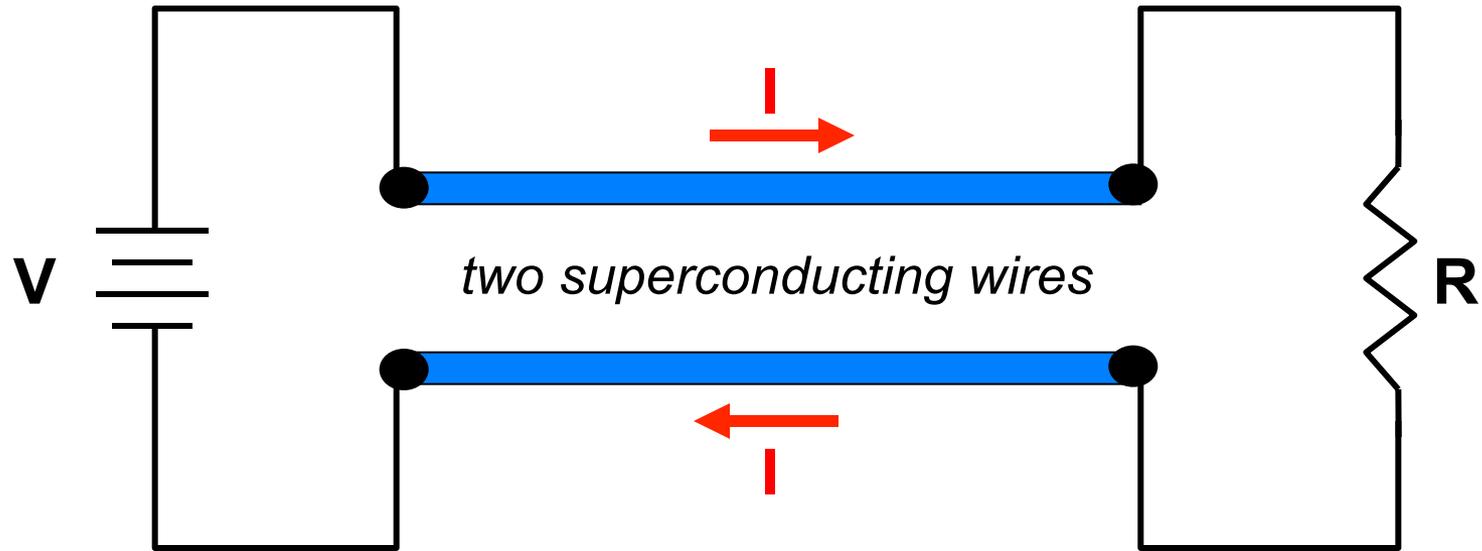

## The mechanism

*Excitons are launched and absorbed via Andreev reflection.  
Excitons transport energy but not charge.*

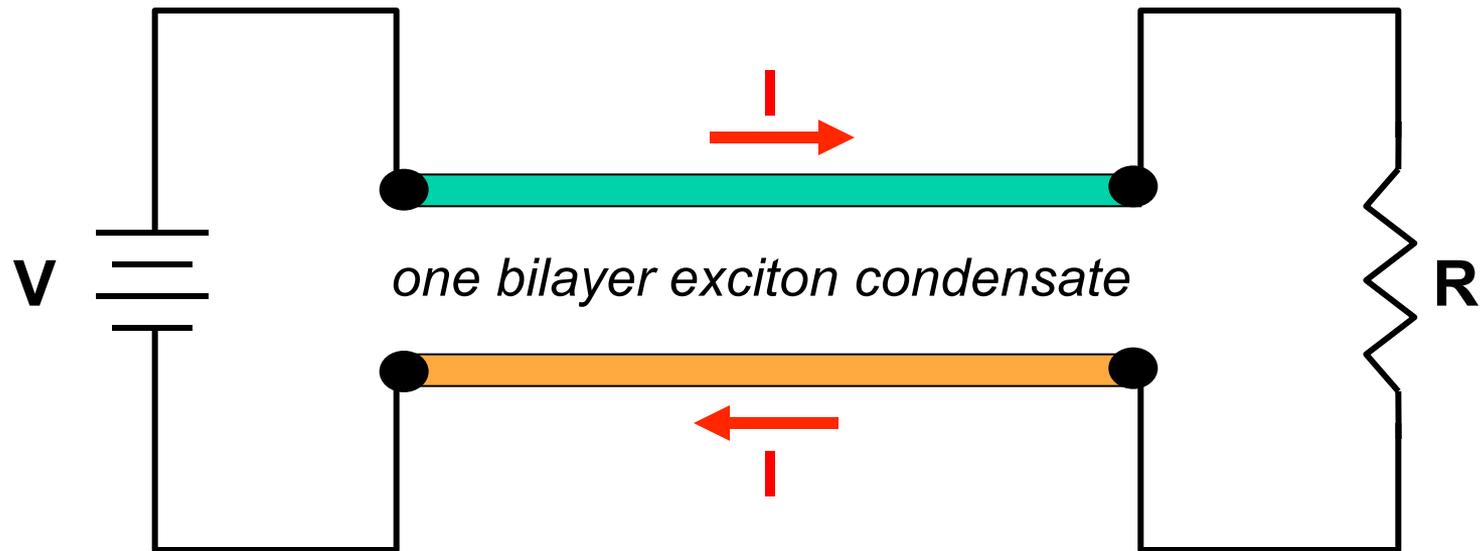

# Analogy to superconductivity

$$\Delta\phi = \frac{eV}{\hbar}t + kx$$

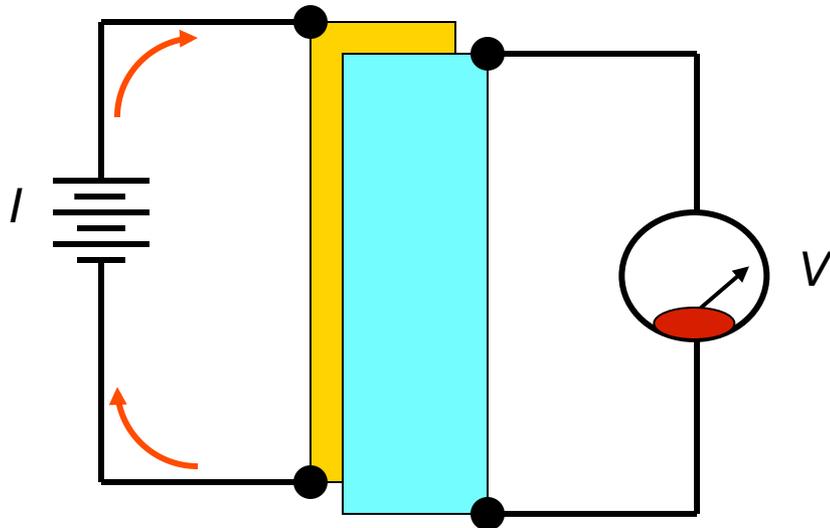

# Analogy to superconductivity

$$\phi = \frac{eV}{\hbar} t + kx$$

## Coulomb Drag

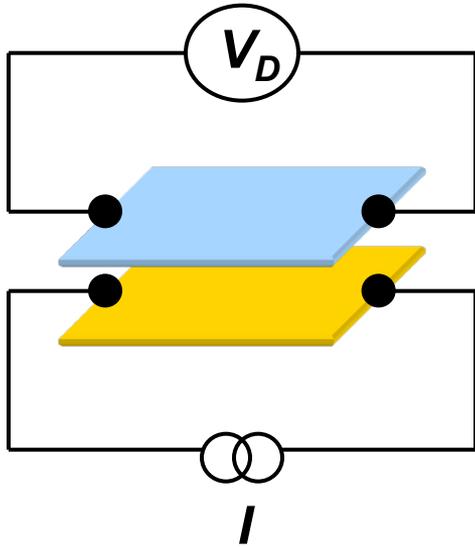

$$R_D \equiv \frac{V}{I}$$

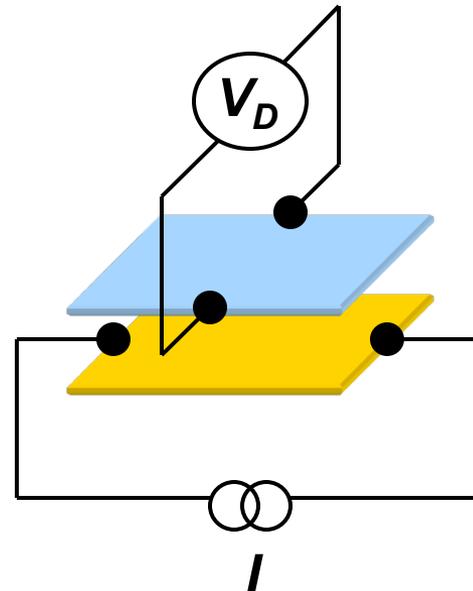

*Usually a weak, perturbative effect.*

# Coulomb drag in magnetic fields

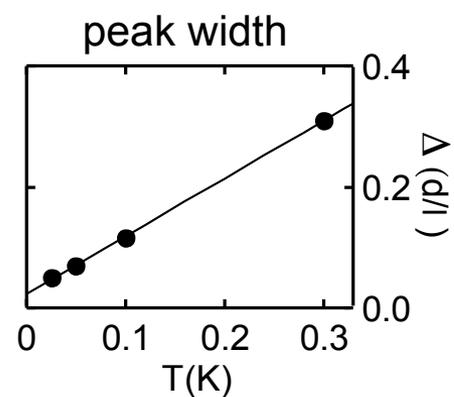

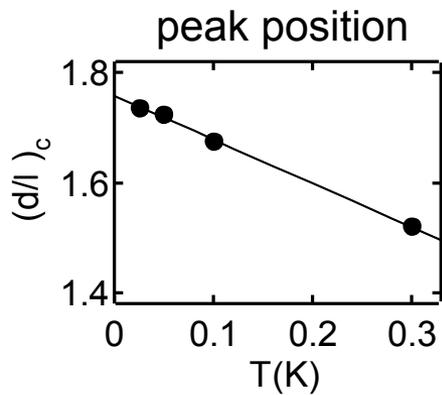

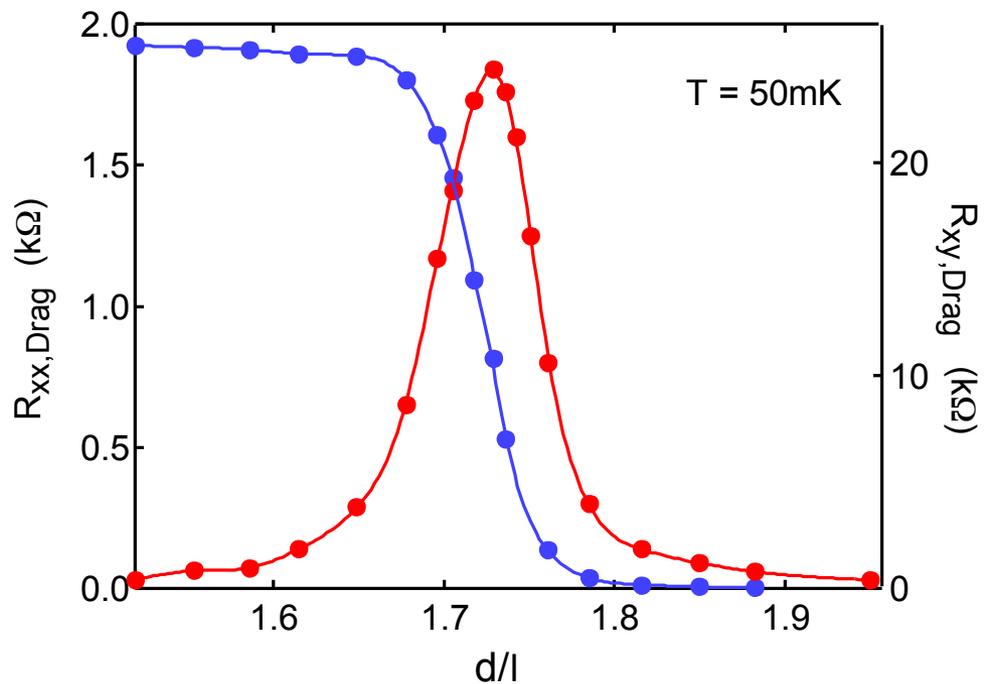

*Longitudinal drag*

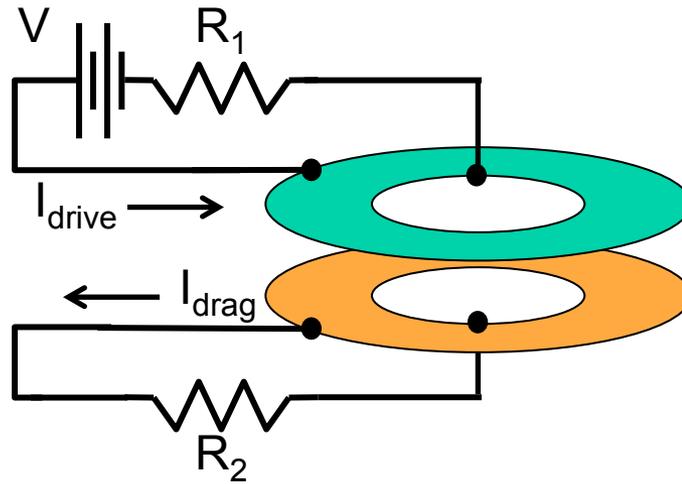

*Hall drag*

# Drag Coefficients at $\nu_T = 1$

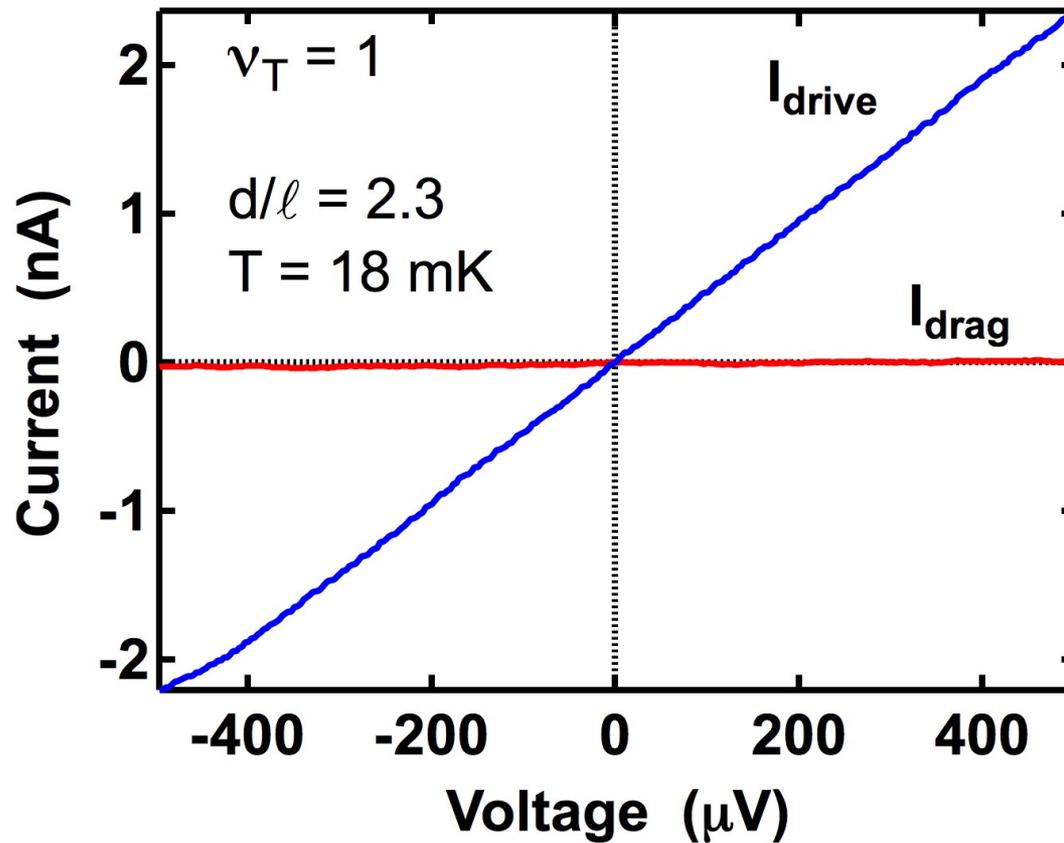

# Corbino Coulomb Drag

Su & MacDonald 2008

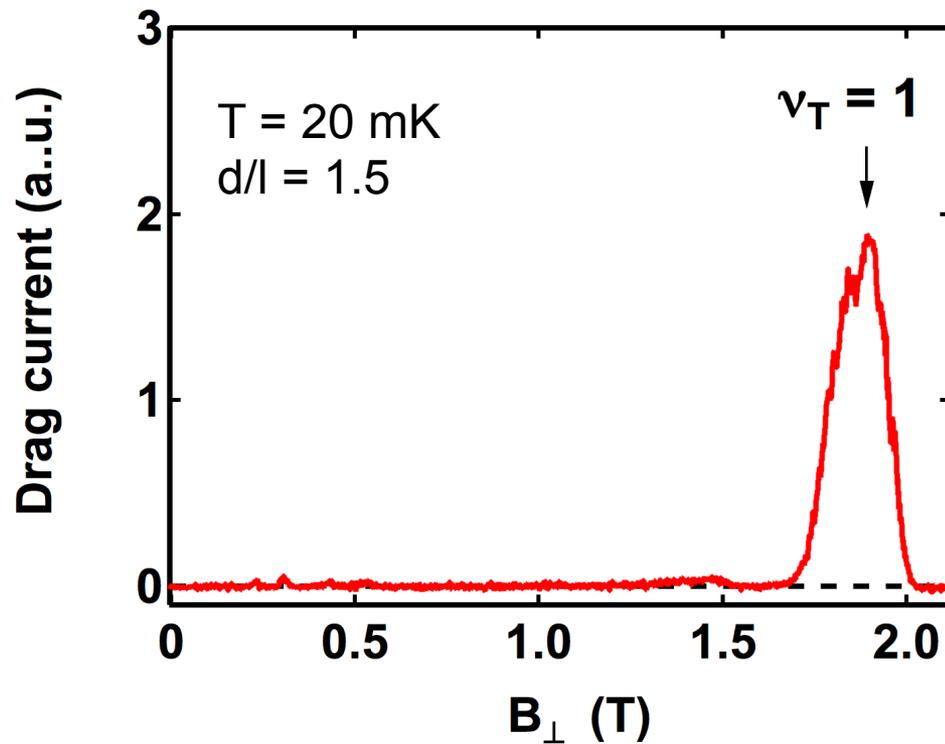

*Corbino Coulomb Drag:  
Incoherent Phase*

*Negligible drag current when layers are independent.*

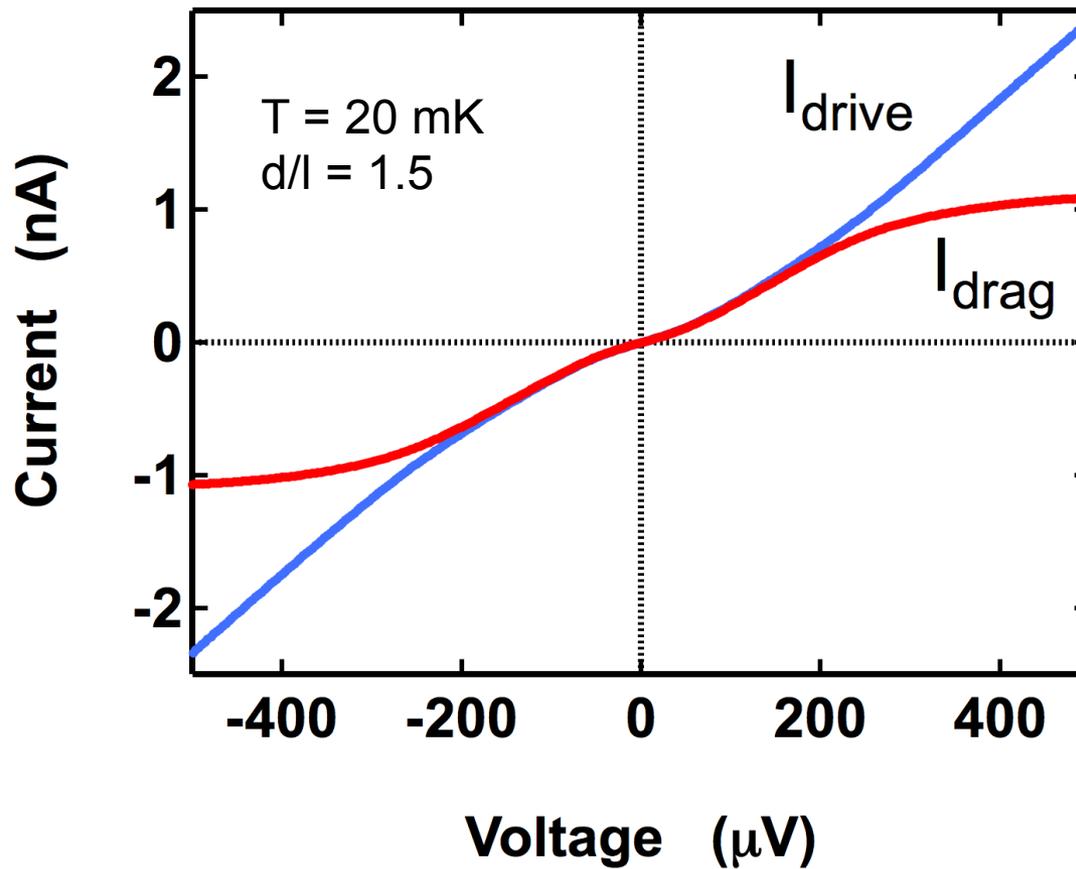

## Corbino Coulomb Drag: Coherent Phase

Significant drag only at  $\nu_T = 1$

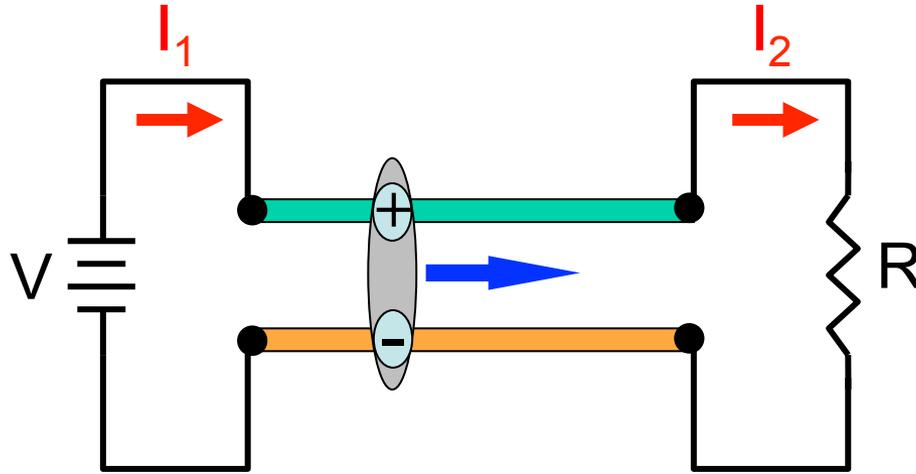

*Corbino Coulomb Drag:  
Coherent Phase*

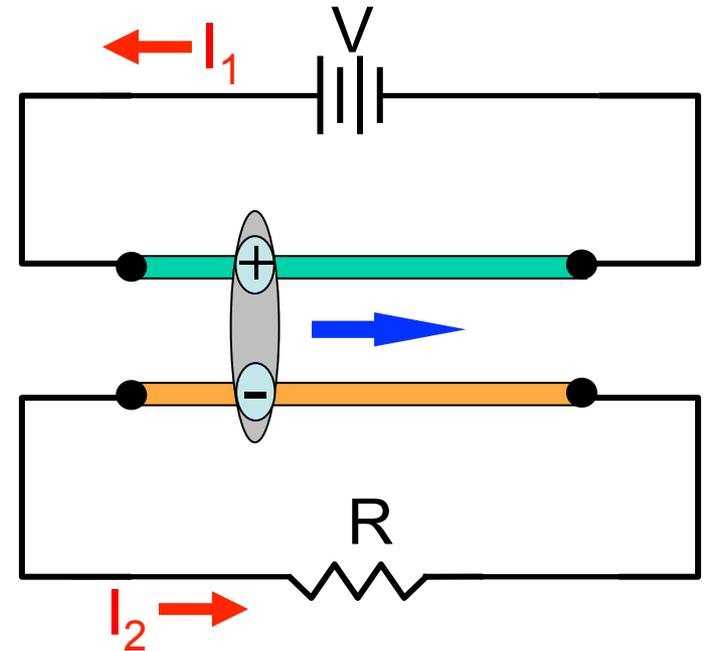

*Drag and drive currents equal at small V.  
"Perfect" Coulomb Drag*

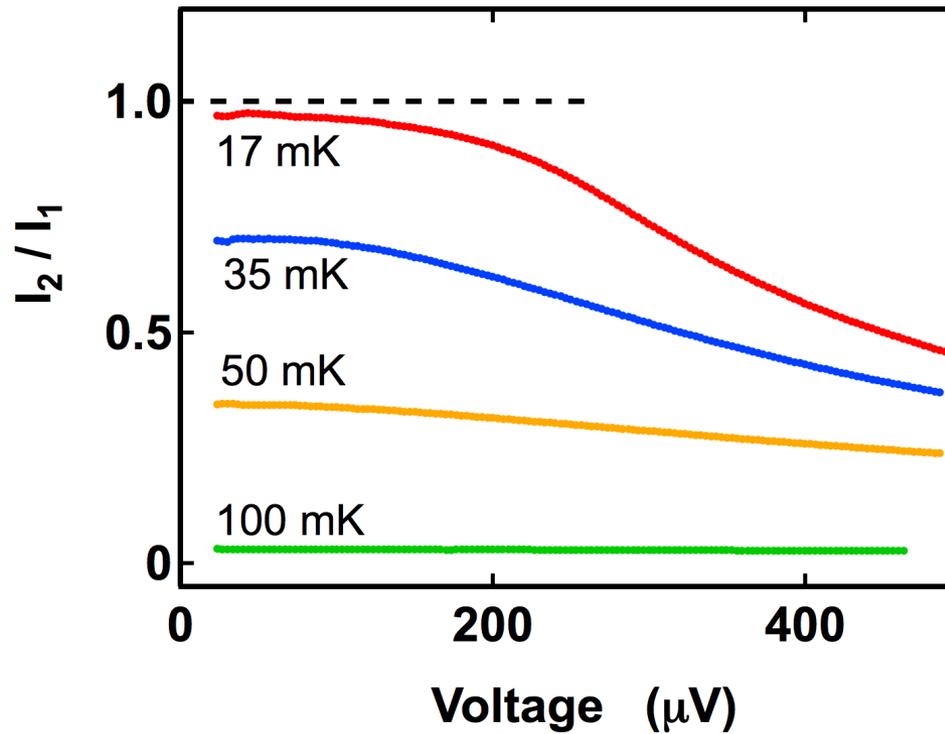

# Inducing exciton transport

Ideally,  $I_1 = I_2$

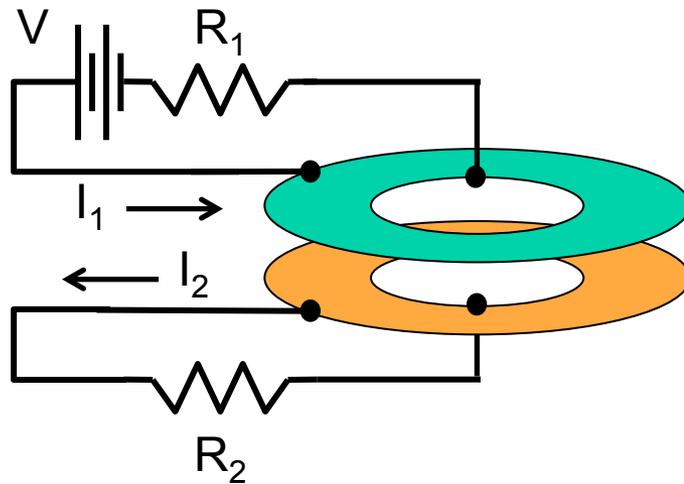

## Breakdown of Perfect Coulomb Drag

When  $I_1 \neq I_2$ , there is charge transport across annulus.

## Modeling the Breakdown

Su-MacDonald 1D model:

$$\sigma_{xx}^{\text{CF}} = \infty$$

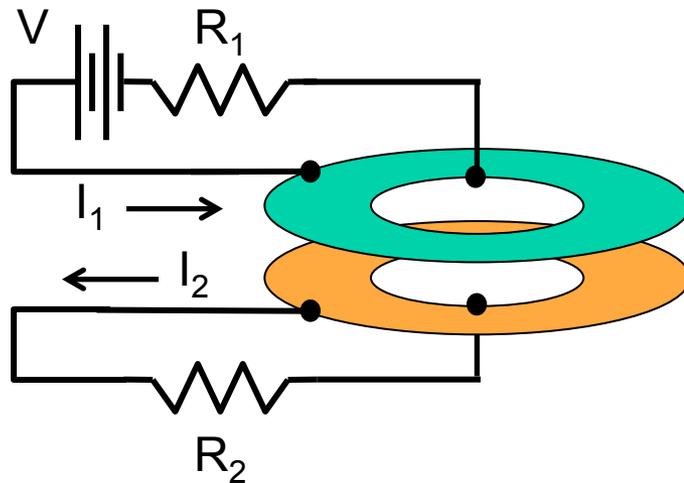

$$\sigma_{xx}^{\parallel} = 0$$

$$R_1 + R_2 \geq 2h/e^2$$

$$I_2 = I_1 = \frac{V}{R_1 + R_2}$$

## Modeling the Breakdown

Generalized Su-MacDonald model:

$$\sigma_{xx}^{CF} = \infty$$

$$\sigma_{xx}^{\parallel} > 0$$

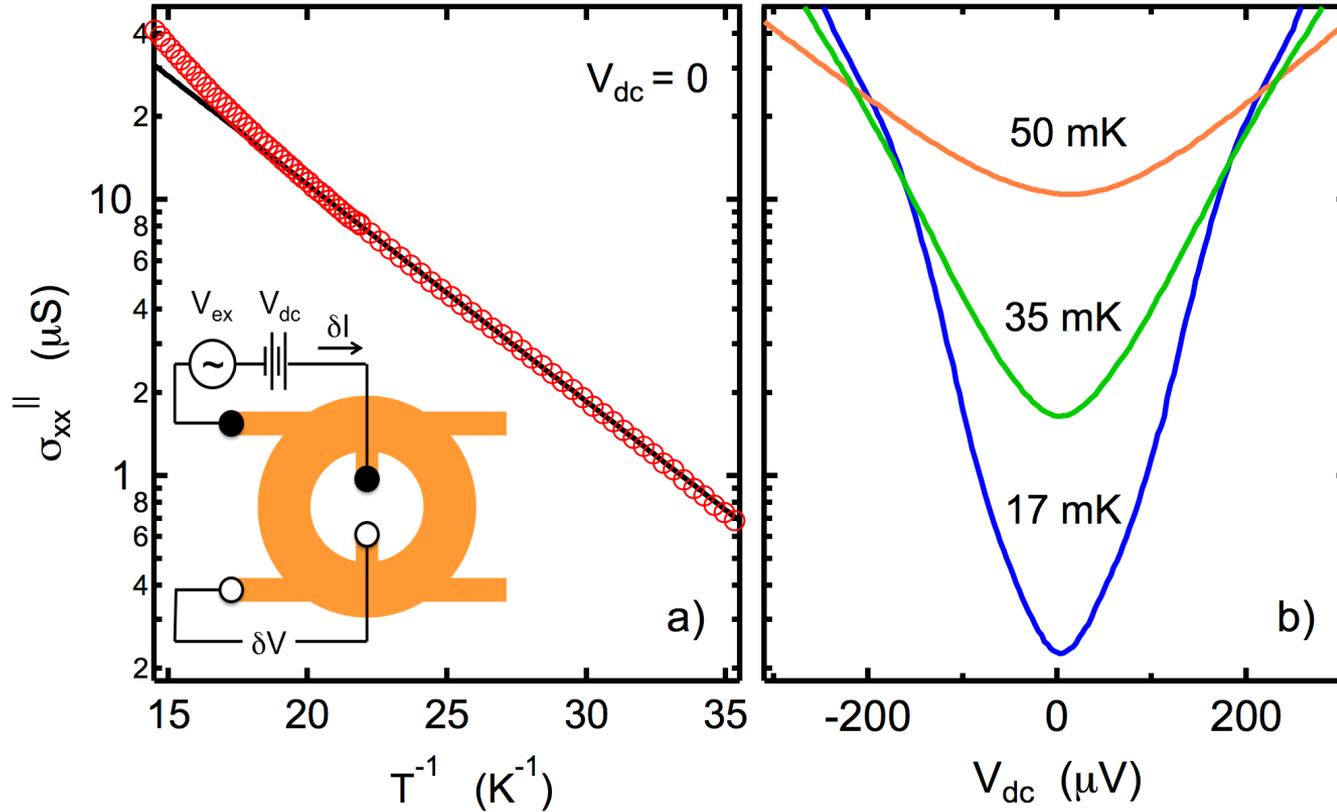

$$R_1 + R_2 \geq 2h/e^2$$

$$I_2 = \frac{V}{R_1 + R_2 + R_1 R_2 \sigma_{xx}^{\parallel}}$$

$$\frac{I_2}{I_1} = \frac{1}{1 + R_2 \sigma_{xx}^{\parallel}}$$

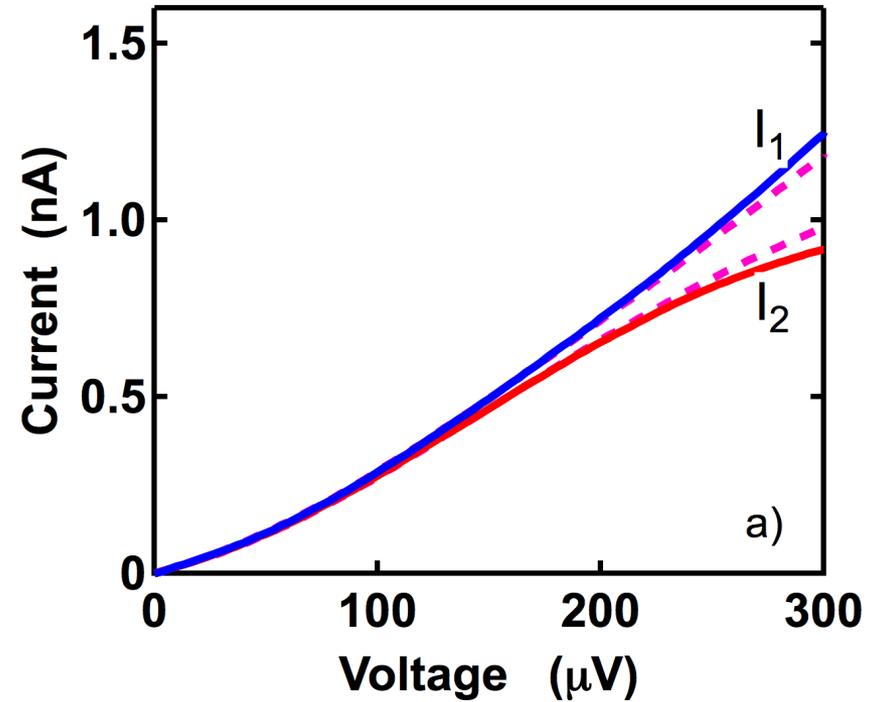

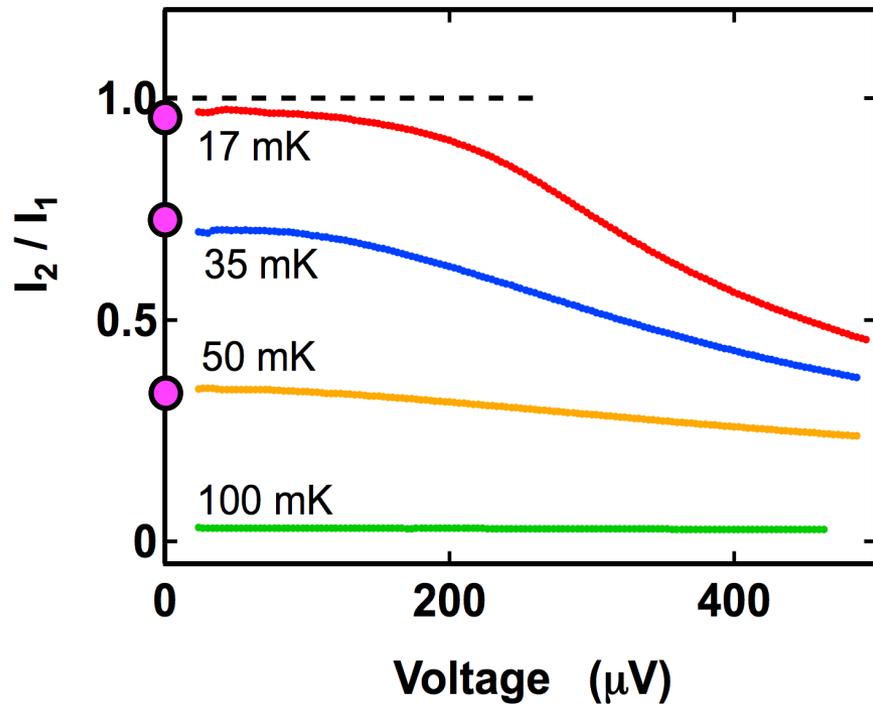

# Charged quasiparticle transport

Charge gap  $\Delta \approx 360 \text{ mK}$

## Model vs. Experiment

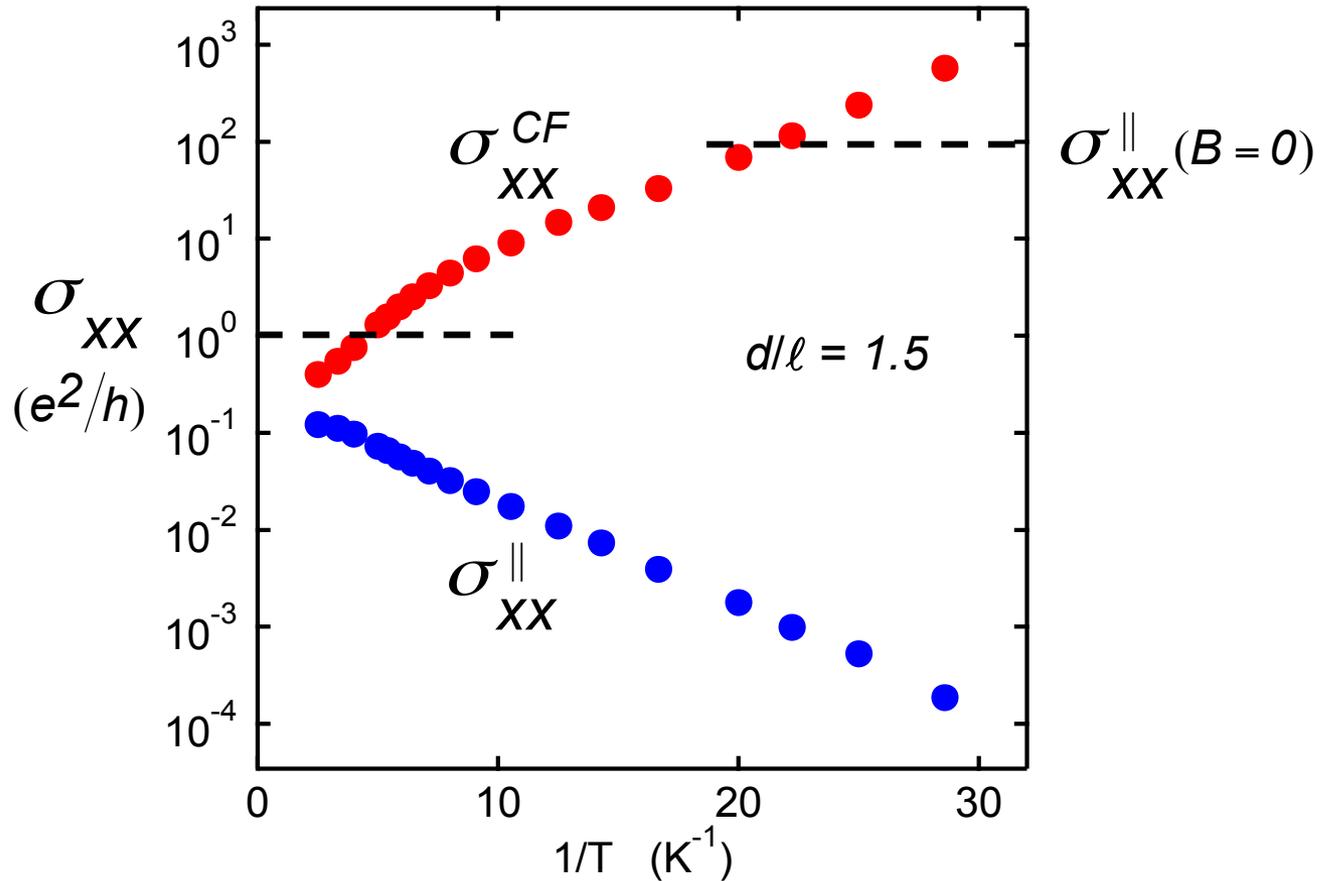

Combined condensate and quasiparticle transport

dissipation in counterflow

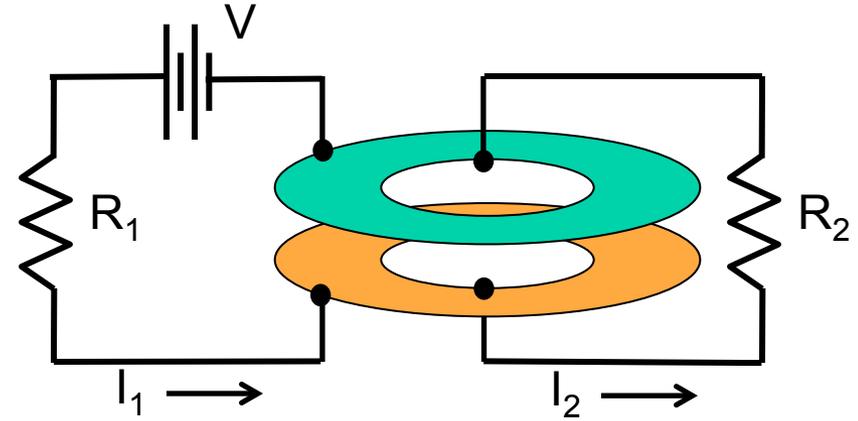

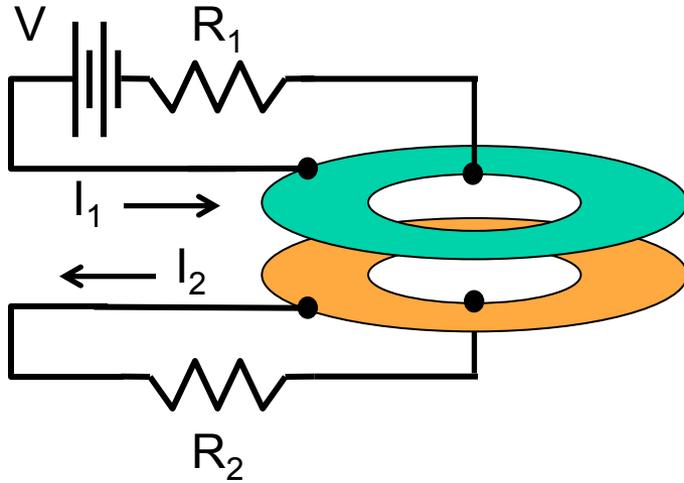

# Hall Bar Counterflow Experiment

*But do Hall bars really detect bulk exciton dissipation?*

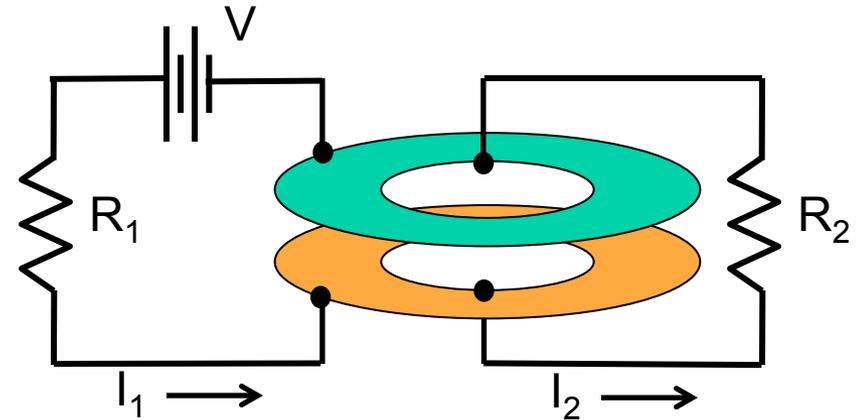

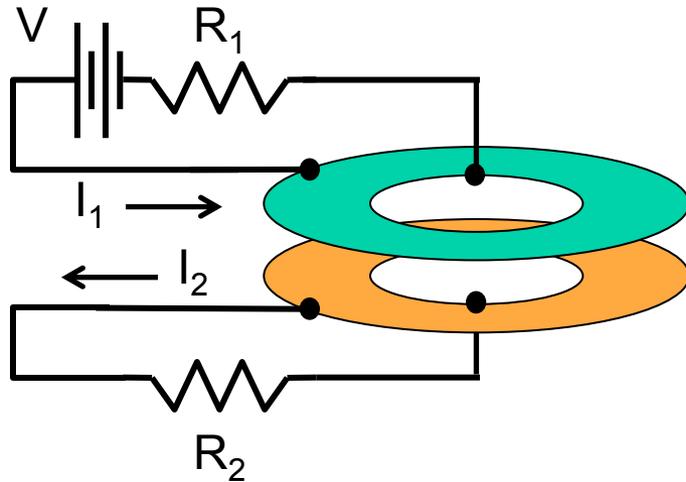

## Exciton dissipation masked by extrinsic series resistances

$$I_2 = I_1 = \frac{V}{R_1 + R_2}$$

## Exciton dissipation masked by extrinsic series resistances

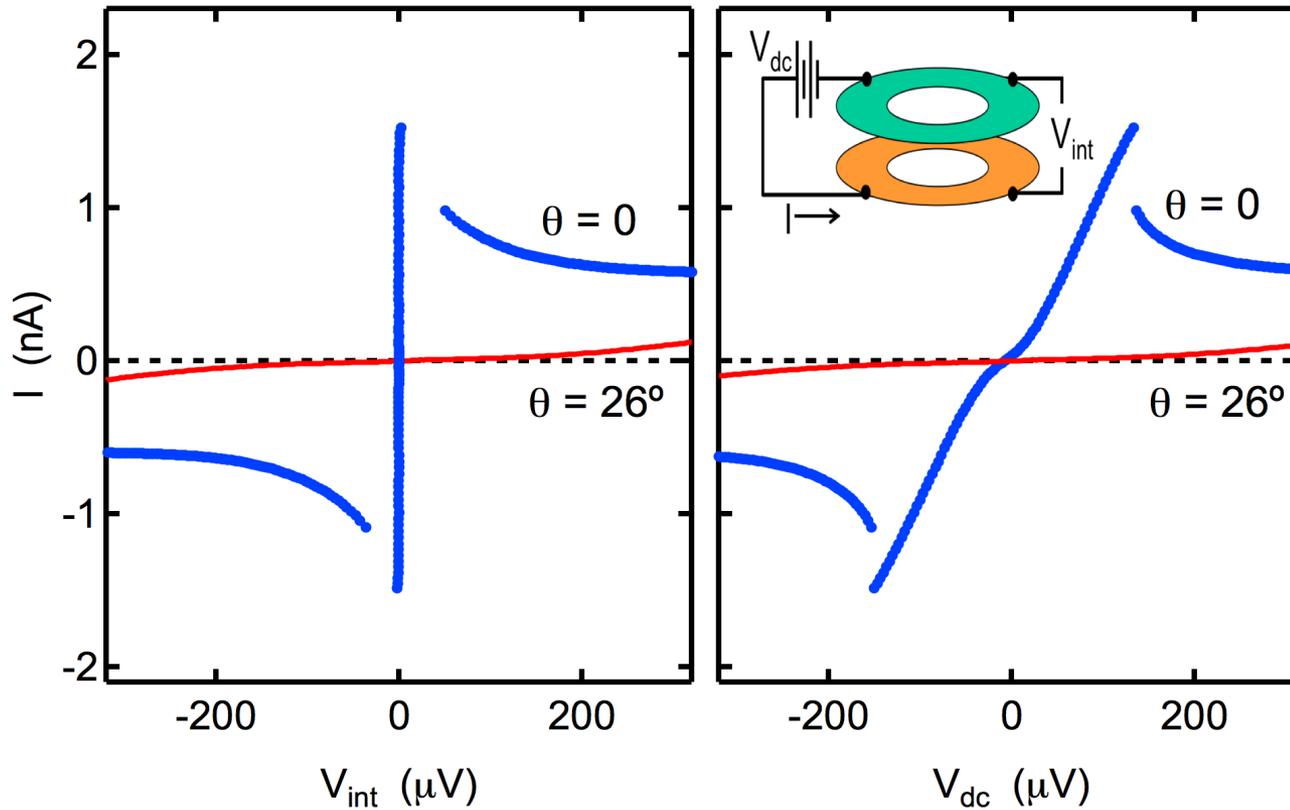

$$I_2 = I_1 = \frac{V}{R_1 + R_2 + R_{\text{ex}}}$$

How can we determine  $R_1$  and  $R_2$ ?

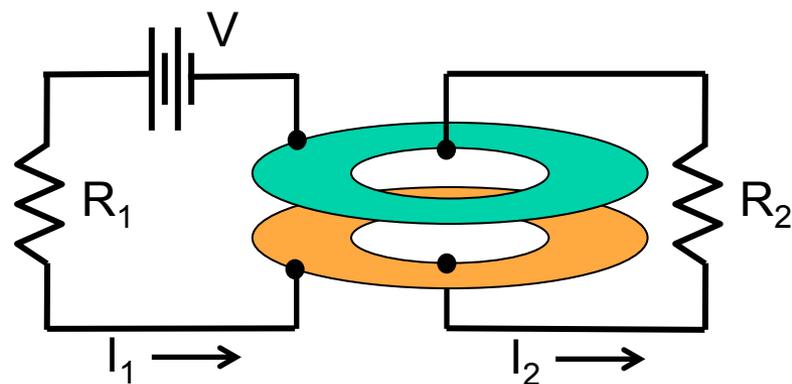

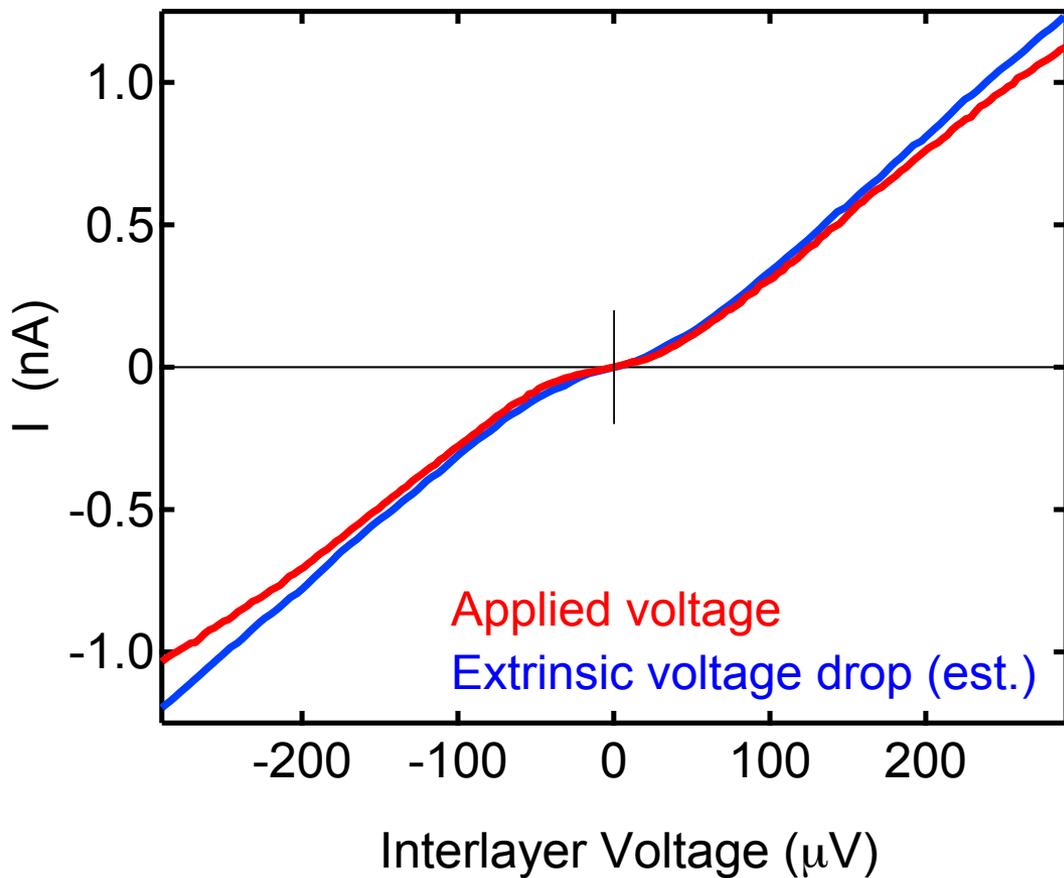

## Tunneling: 2-terminal vs. 4-terminal

At  $\theta = 0$ , 2-terminal I-V dominated by series resistances.

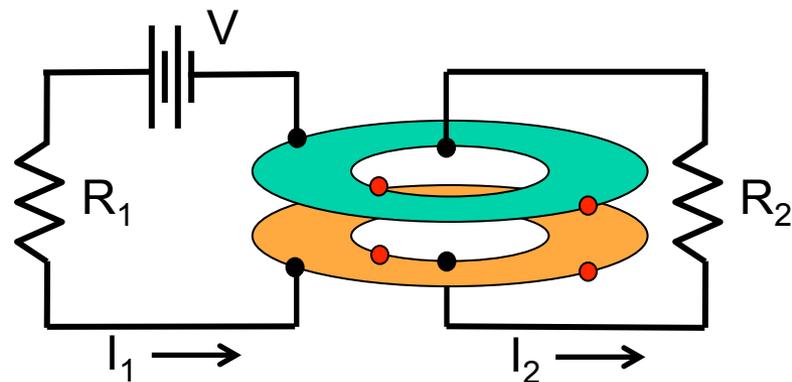

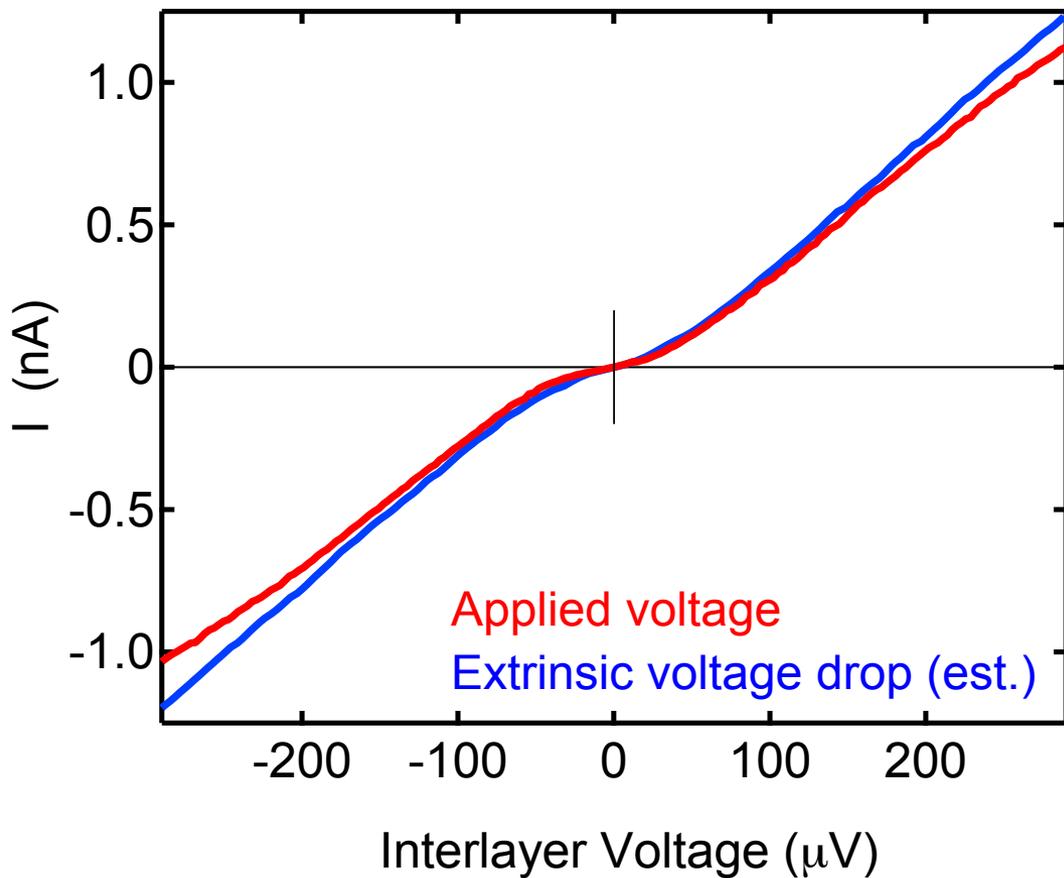

*Exciton dissipation "small"*

*New, multi-terminal measurements needed.*

*Exciton dissipation "small"*

*New, multi-terminal measurements needed.*

## Conclusions

*Direct observation of exciton transport across insulating bulk of the bilayer  $\nu_T = 1$  QHE state.*

*Energy transport without charge transport.*

*“Perfect” Coulomb drag at low  $T$ ,  $d/l$ , and  $V$ .*

## Questions

*Dissipation in exciton transport is small, but how small? Can we detect the  $KT$  transition?*

*Exciton transport is coherent. But on what length scale?*

*Can we make an excitonic Josephson junction?*
